CHAPTER 1

TRANSVERSE VIBRATION EQUATIONS

The different assumptions and corresponding theories of transverse vibrations of beams are presented. The dispersive equation, its corresponding curve ‘propagation constant–frequency’ and its comparison with the exact dispersive curve are presented for each theory and discussed.

The exact dispersive curve corresponds to the first and second antisymmetrical Lamb’s wave.

NOTATION

c_b	Velocity of longitudinal wave, $c_b = \sqrt{E/\rho}$
c_t	Velocity of shear wave, $c_t = \sqrt{G/\rho}$
D_0	Stiffness parameter, $D_0^4 = EI_z/(2\rho H)$
E, v, ρ	Young's modulus, Poisson's ratio and density of the beam material
E_1, G	Longitudinal and shear modulus of elasticity, $E_1 = E/(1 - v^2)$, $G = E/2(1 + v)$
F_y	Shear force
H	Height of the plate
I_z	Moment of inertia of a cross-section
k	Propagation constant
k_b	Longitudinal propagation constant, $k_b = \omega/c_b$
k_t	Shear propagation constant, $k_t = \omega/c_t$
k_0	Bending wave number for Bernoulli–Euler rod, $k_0^4 = \omega^2/D_0^4$
M	Bending moment
p, q	Correct multipliers
u_x, u_y	Longitudinal and transversal displacements
w, ψ	Average displacement and average slope
x, y, z	Cartesian coordinates
σ_{xx}, σ_{xy}	Longitudinal and shear stress
μ_t, λ	Dimensionless parameters, $\mu_t = k_t H$, $\lambda = kH$
ω	Natural frequency
$(\cdot) = \frac{d}{dx}$	Differentiation with respect to space coordinate
$(\cdot) = \frac{d}{dt}$	Differentiation with respect to time

1.1 AVERAGE VALUES AND RESOLVING EQUATIONS

The different theories of dynamic behaviours of beams may be obtained from the equations of the theory of elasticity, which are presented with respect to average values. The object under study is a thin plate with rectangular cross-section (Figure 1.1).

1.1.1 Average values for deflections and internal forces

1. Average displacement and slope are

$$w = \int_{-H}^{+H} \frac{u_y}{2H} dy \quad (1.1)$$

$$\psi = \int_{-H}^{+H} \frac{yu_x}{I_z} dy \quad (1.2)$$

where u_x and u_y are longitudinal and transverse displacements.

2. Shear force and bending moment are

$$F_y = \int_{-H}^{+H} \sigma_{xy} dy \quad (1.3)$$

$$M = \int_{-H}^{+H} y\sigma_{xx} dy \quad (1.4)$$

where σ_x and σ_y are the normal and shear stresses that correspond to u_x and u_y .

Resolving the equations may be presented in terms of average values as follows (Landau and Lifshitz, 1986)

1. Integrating the equilibrium equation of elasticity theory leads to

$$2\rho H \ddot{w} = F'_y \quad (1.5)$$

$$\rho I_z \ddot{\psi} = M'_z - F_y \quad (1.6)$$

2. Integrating Hooke's equation for the plane stress leads to

$$F_y = 2HG \left[w' + \frac{u_x(H)}{H} \right] \quad (1.7)$$

$$M_z = E_1 \left\{ I_z \psi' + 2Hv [u_y(H) - w] \right\} = EI_z \psi' + v \int_{-H}^{+H} y\sigma_{yy} dy \quad (1.7a)$$

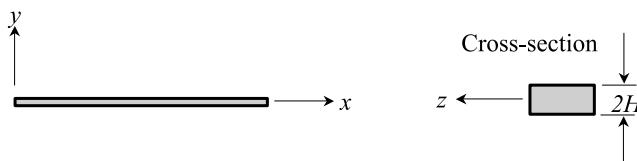

FIGURE 1.1. Thin rectangular plate, the boundary conditions are not shown.

Equations (1.5)–(1.7a) are complete systems of equations of the theory of elasticity with respect to average values w , ψ , F_y and M . These equations contain two redundant unknowns $u_x(H)$ and $u_y(H)$. Thus, to resolve the above system of equations, additional equations are required. These additional equations may be obtained from the assumptions accepted in approximate theories.

The solution of the governing differential equation is

$$w = \exp(ikx - i\omega t) \quad (1.8)$$

where k is a propagation constant of the wave and ω is the frequency of vibration.

The degree of accuracy of the theory may be evaluated by a dispersive curve $k - \omega$ and its comparison with the exact dispersive curve. We assume that the exact dispersive curve is one that corresponds to the first and second antisymmetric Lamb's wave. The closer the dispersive curve for a specific theory to the exact dispersive curve, the better the theory describes the vibration process (Artobolevsky *et al.* 1979).

1.2 FUNDAMENTAL THEORIES AND APPROACHES

1.2.1 Bernoulli–Euler theory

The Bernoulli–Euler theory takes into account the inertia forces due to the transverse translation and neglects the effect of shear deflection and rotary inertia.

Assumptions

1. The cross-sections remain plane and orthogonal to the neutral axis ($\psi = -w'$).
2. The longitudinal fibres do not compress each other ($\sigma_{yy} = 0$, $\rightarrow M_z = EI_z\ddot{\psi}$).
3. The rotational inertia is neglected ($\rho I_z\ddot{\psi} = 0$). This assumption leads to

$$F_y = M'_z = -EI_z w'''$$

Substitution of the previous expression in Equation (1.5) leads to the differential equation describing the transverse vibration of the beam

$$\frac{\partial^4 w}{\partial x^4} + \frac{1}{D_0^4} \frac{\partial^2 w}{\partial t^2} = 0, \quad D_0^4 = \frac{EI_z}{2\rho H} \quad (1.9)$$

Let us assume that displacement w is changed according to Equation (1.8). The dispersive equation which establishes the relationship between k and ω may be presented as

$$k^4 = \frac{\omega^2}{D_0^4} = k_0^4$$

This equation has two roots for a forward-moving wave in a beam and two roots for a backward-moving wave. Positive roots correspond to a forward-moving wave, while negative roots correspond to a backward-moving wave.

The results of the dispersive relationships are shown in Figure 1.2. Here, bold curves 1 and 2 represent the exact results. Curves 1 and 2 correspond to the first and second

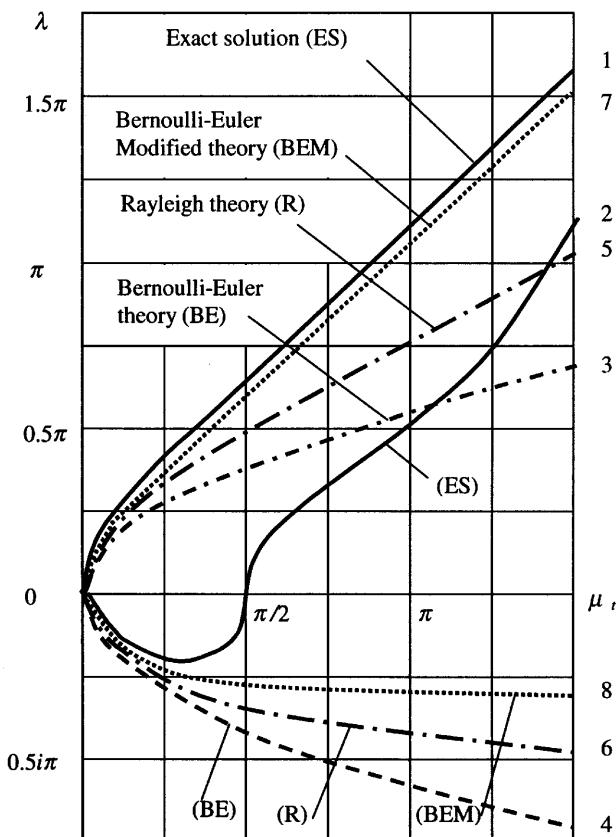

FIGURE 1.2. Transverse vibration of beams. Dispersive curves for different theories. 1, 2—Exact solution; 3, 4—Bernoulli–Euler theory; 5, 6—Rayleigh theory, 7, 8—Bernoulli–Euler modified theory.

antisymmetric Lamb's wave, respectively. The second wave transfers from the imaginary zone into the real one at $k_t H = \pi/2$. Curves 3 and 4 are in accordance with the Bernoulli–Euler theory. Dispersion obtained from this theory and dispersion obtained from the exact theory give a close result when frequencies are close to zero. This elementary beam theory is valid only when the height of the beam is small compared with its length (Artobolevsky *et al.*, 1979).

1.2.2 Rayleigh theory

This theory takes into account the effect of rotary inertia (Rayleigh, 1877).

Assumptions

1. The cross-sections remain plane and orthogonal to the neutral axis ($\psi = -w'$).

2. The longitudinal fibres do not compress each other ($\sigma_{yy} = 0$, $M_z = EI_z\psi'$).

From Equation (1.6) the shear force $F_y = M'_z - \rho I_z \ddot{\psi}$.

Differential equation of transverse vibration of the beam

$$\frac{\partial^4 w}{\partial x^4} + \frac{1}{D_0^4} \frac{\partial^2 w}{\partial t^2} - \frac{1}{c_b^2} \frac{\partial^4 w}{\partial x^2 \partial t^2} = 0, \quad c_b^2 = \frac{E}{\rho} \quad (1.10)$$

where c_b is the velocity of longitudinal waves in the thin rod.

The last term on the left-hand side of the differential equation describes the effect of the rotary inertia.

The dispersive equation may be presented as follows

$$2k_{1,2}^2 = k_b^2 \pm \sqrt{k_b^2 + 4k_0^4}$$

where k_0 is the wave number for the Bernoulli–Euler rod, and k_b is the longitudinal wave number.

Curves 5 and 6 in Figure 1 reflect the effect of rotary inertia.

1.2.3 Bernoulli–Euler modified theory

This theory takes into account the effect of shear deformation; rotational inertia is negligible (Bernoulli, 1735, Euler, 1744). In this case, the cross-sections remain plane, but not orthogonal to the neutral axis, and the differential equation of the transverse vibration is

$$\frac{\partial^4 y}{\partial x^4} + \frac{1}{D_0^4} \frac{\partial^2 y}{\partial t^2} - \frac{1}{c_t^2} \frac{\partial^4 y}{\partial x^2 \partial t^2} = 0, \quad c_t^2 = \frac{G}{\rho} \quad (1.11)$$

where c_t is the velocity of shear waves in the thin rod.

The dispersive equation may be presented as follows

$$2k_{1,2}^2 = k_t^2 \pm \sqrt{k_t^2 + 4k_0^4}, \quad k_t^2 = \frac{\omega^2}{c_t^2}$$

Curves 7 and 8 in Figure 1.2 reflect the effect of shear deformation.

The Bernoulli–Euler theory gives good results only for low frequencies; this dispersive curve for the Bernoulli–Euler *modified* theory is closer to the dispersive curve for exact theory than the dispersive curve for the Bernoulli–Euler theory; the Rayleigh theory gives a worse result than the modified Bernoulli–Euler theory.

Curves 1 and 2 correspond to the first and second antisymmetric Lamb's wave, respectively. The second wave transfers from the imaginary domain into the real one at $k_t H = \pi/2$.

1.2.4 Bress theory

This theory takes into account the rotational inertia, shear deformation and their combined effect (Bress, 1859).

Assumptions

1. The cross-sections remain plane.
2. The longitudinal fibres do not compress each other ($\sigma_{yy} = 0$).

Differential equation of transverse vibration

$$\frac{\partial^4 w}{\partial x^4} + \frac{1}{D_0^4} \frac{\partial^2 w}{\partial t^2} - \left(\frac{1}{c_b^2} + \frac{1}{c_t^2} \right) \frac{\partial^4 w}{\partial x^2 \partial t^2} + \frac{1}{c_b^2 c_t^2} \frac{\partial^4 w}{\partial t^4} = 0 \quad (1.12)$$

In this equation, the third and fourth terms reflect the rotational inertia and the shear deformation, respectively. The last term describes their combined effect; this term leads to the occurrence of a cut-off frequency of the model, which is a recently discovered fundamental property of the system.

1.2.5 Volterra theory

This theory, as with the Bress theory, takes into account the rotational inertia, shear deformation and their combined effect (Volterra, 1955).

Assumption

All displacements are linear functions of the transverse coordinates

$$u_x(x, y, t) = y\psi(x, t), \quad u_y(x, y, t) = w(x, t)$$

In this case the bending moment and shear force are

$$M_z = E_1 I_z \psi, \quad F_y = 2HG(w' + \psi)$$

Differential equation of transverse vibration

$$\frac{\partial^4 w}{\partial x^4} + \frac{1 - v^2}{D_0^4} \frac{\partial^2 w}{\partial t^2} - \left(\frac{1}{c_s^2} + \frac{1}{c_t^2} \right) \frac{\partial^4 w}{\partial x^2 \partial t^2} + \frac{1}{c_s^2 c_t^2} \frac{\partial^4 w}{\partial t^4} = 0 \quad (1.13)$$

where c_s is the velocity of a longitudinal wave in the thin plate, $c_s^2 = (E_1/\rho)$, and E_1 is the longitudinal modulus of elasticity, $E_1 = (E/1 - v^2)$.

Difference between Volterra and Bress theories. As is obvious from Equations (1.12) and (1.13), the bending stiffness of the beam according to the Volterra model is $(1 - v^2)^{-1}$ times greater than that given by the Bress theory (real rod). This is because transverse compressive and tensile stresses are not allowed in the Volterra model.

1.2.6 Ambartsumyan theory

The Ambartsumyan theory allows the distortion of the cross-section (Ambartsumyan, 1956).

Assumptions

1. The transverse displacements for all points in the cross-section are equal: $\partial u_y / \partial y = 0$.

2. The shear stress is distributed according to function $f(y)$:

$$\sigma_{xy}(x, y, t) = G\varphi(x, t)f(y)$$

In this case, longitudinal and transverse displacements may be given as

$$u_x(x, y, t) = -y \frac{\partial w(x, t)}{\partial x} + \varphi(x, t)g(y)$$

$$u_y(x, y, t) = w(x, t), \quad g(y) = \int_0^y f(\xi) d\xi$$

Differential equation of transverse vibration

$$\frac{\partial^4 w}{\partial x^4} + \frac{1 - v^2}{D_0^4} \frac{\partial^2 w}{\partial t^2} - \left(\frac{1}{c_s^2} + \frac{1}{ac_t^2} \right) \frac{\partial^4 w}{\partial x^2 \partial t^2} + \frac{1}{ac_s^2 c_t^2} \frac{\partial^4 w}{\partial t^4} = 0 \quad (1.14)$$

where

$$a = \frac{II_1}{2HI_0}, \quad I_1 = \int_{-H}^H f(\xi) d\xi, \quad I_0 = \int_{-H}^H yg(y) dy$$

Difference between Ambartsumyan and Volterra theories. The Ambartsumyan's differential equation differs from the Volterra equation by coefficient a at c_t^2 . This coefficient depends on $f(y)$.

Special cases

1. Ambartsumyan and Volterra differential equations coincide if $f(y) = 0.5$.
2. If shear stresses are distributed by the law $f(y) = 0.5(H^2 - y^2)$ then $a = 5/6$.
3. If shear stresses are distributed by the law $f(y) = 0.5(H^{2n} - y^{2n})$, then $a = (2n + 3)/(2n + 4)$.

1.2.7 Vlasov theory

The cross-sections have a distortion, but after deformation the cross-sections remain perpendicular to the surfaces $y = \pm H$ (Vlasov, 1957).

Assumptions

1. The longitudinal and transversal displacements are

$$u_x(x, y, t) = -\varepsilon y - \frac{y^2}{2H^2G} \sigma_{xy}^0$$

$$u_y(x, y, t) = w(x, y, t)$$

where $\varepsilon = -(\partial u_x / \partial y)_{y=0}$ and σ_{xy}^0 is the shear stress at $y = 0$.

This assumption means that the change in shear stress by the quadratic law is

$$\sigma_{xy} = \sigma_{xy}^0 \left(1 - \frac{y^2}{H^2} \right)$$

2. The cross-sections are curved but, after deflection, they remain perpendicular to the surfaces at

$$y = H \quad \text{and} \quad y = -H$$

This assumption corresponds to expression

$$\left(\frac{\partial u_x}{\partial y} \right)_{y=\pm H} = 0$$

These assumptions of the Vlasov and Ambartsumyan differential equations coincide at parameter $a = 5/6$. Coefficient a is the improved dispersion properties on the higher bending frequencies.

1.2.8 Reissner, Goldenveizer and Ambartsumyan approaches

These approaches allow transverse deformation, so differential equations may be developed from the Bress equation if additional coefficient a is put before c_t^2 .

Assumptions

1. $\sigma_{yy} = 0$.
2. $\sigma_{xy} = (x, y, t) = G\varphi(x, t)f(y)$.

These assumptions lead to the Bress equation (1.12) with coefficient a instead of c_t^2 . The structure of this equation coincides with the Timoshenko equation (Reissner, 1945; Goldenveizer, 1961; Ambartsumyan, 1956).

1.2.9 Timoshenko theory

The Timoshenko theory takes into account the rotational inertia, shear deformation and their combined effects (Timoshenko, 1921, 1922, 1953).

Assumptions

1. Normal stresses $\sigma_{yy} = 0$; this assumption leads to the expression for the bending moment

$$M_z = EI_z \frac{\partial \psi}{\partial x}$$

2. The ratio $u_x(H)/H$ substitutes for angle ψ ; this means that the cross-sections remain plane. This assumption leads to the expression for shear force

$$F_y = 2qHG \left(\frac{\partial w}{\partial x} + \psi \right)$$

3. The fundamental assumption for the Timoshenko theory: arbitrary shear coefficient q enters into the equation.

Mechanical presentation of the Timoshenko beam. A beam can be substituted by the set of rigid non-deformable plates that are connected to each other by elastic massless pads.

The complete set of the basic relationships

$$\begin{aligned} 2\rho H \ddot{w} &= F'_y \\ \rho I_z \ddot{\psi} &= M'_z - F_y \\ M_z &= EI_z \frac{\partial \psi}{\partial x} \\ F_y &= 2qHG \left(\frac{\partial w}{\partial x} + \psi \right) \end{aligned}$$

To obtain the differential equation of vibration eliminate from the basic relationships all variables except displacement.

Timoshenko differential equation of the transverse vibration of a beam

$$\frac{\partial^4 w}{\partial x^4} + \frac{1}{D_0^4} \frac{\partial^2 w}{\partial t^2} - \left(\frac{1}{c_b^2} + \frac{1}{qc_t^2} \right) \frac{\partial^4 w}{\partial x^2 \partial t^2} + \frac{1}{qc_b^2 c_t^2} \frac{\partial^4 w}{\partial t^4} = 0 \quad (1.15)$$

The fundamental difference between the Rayleigh and Bress theories, on one hand, and the Timoshenko theory, on the other, is that the correction factor in the Rayleigh and Bress theories appears as a result of shear and rotary effects, whereas in the Timoshenko theory, the correction factor is introduced in the initial equations. The arbitrary coefficient q is the fundamental assumption in the Timoshenko theory.

Presenting the displacement in the form (1.8) leads to the dispersive equation

$$2k_{1,2}^2 = k_b^2 + \frac{k_t^2}{q} \pm \sqrt{\left(k_b^2 - \frac{k_t^2}{q} \right)^2 + 4k_0^4}$$

where $k_{1,2}$ are propagation constants;

q is the shear coefficient;

k_0 is the wave number of the bending wave in the Bernoulli–Euler rod,

$$k_0^4 = \frac{\omega^2}{D_0^4}, \quad D_0^4 = \frac{EI_z}{2\rho H}$$

k_b and k_t are the longitudinal and shear propagation constants, respectively.

$$k_b^2 = \frac{\omega^2}{c_b^2}, \quad k_t^2 = \frac{\omega^2}{c_t^2}$$

c_b and c_t are the velocities of the longitudinal and shear waves

$$c_b^2 = \frac{E}{\rho}, \quad c_t^2 = \frac{G}{\rho}$$

Practical advantages of the Timoshenko model. Figure 1.3 shows a good agreement between dispersive curves for both the Timoshenko model and the exact curve for high frequencies. This means that the two-wave Timoshenko model describes the vibration of short beams, or high modes of a thin beam, with high precision.

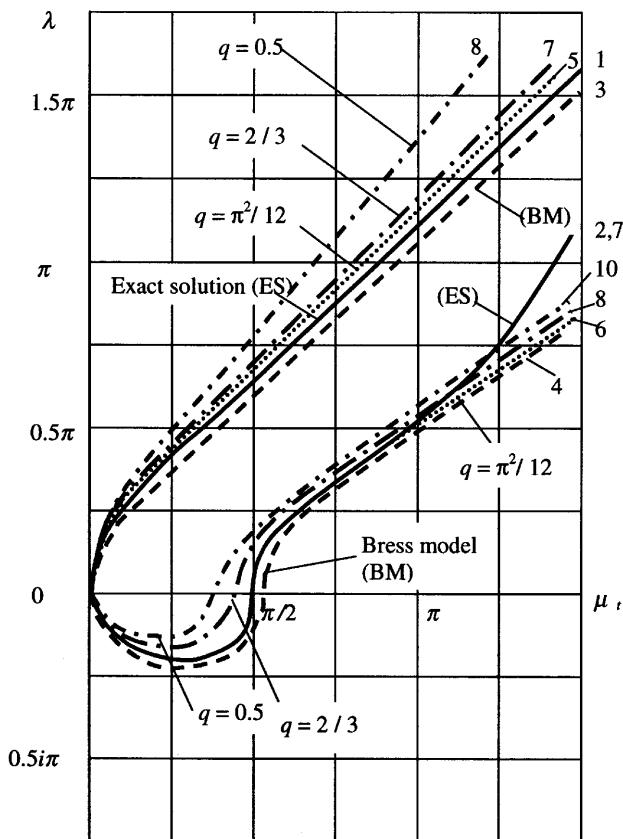

FIGURE 1.3. Dispersive curves for the Timoshenko beam model. 1, 2—exact solution; 3, 4—Bress model; 5, 6— $q = \pi^2/12$; 7, 8— $q = 2/3$; 9, 10— $q = 1/2$.

This type of problem is an important factor in choosing the shear coefficient (Mindlin, 1951; Mindlin and Deresiewicz, 1955).

Figure 1.3 shows the exact curves, 1 and 2, and the dispersive curves for different shear coefficients: curves 3 and 4 correspond to $q = 1$ (Bress theory), curves 5 and 6 to $q = \pi^2/12$, curves 7 and 8 to $q = 2/3$, curves 9 and 10 to $q = 1/2$.

1.2.10 Love theory

The equation of the Love (1927) theory may be obtained from the Timoshenko equation as a special case.

(a) Truncated Love equation

$$\frac{\partial^4 w}{\partial x^4} + \frac{1}{D_0^4} \frac{\partial^2 w}{\partial t^2} - \frac{1}{qc_t^2} \frac{\partial^4 w}{\partial x^2 \partial t^2} = 0, \quad c_t^2 = \frac{G}{\rho} \quad (1.16)$$

(b) Complete Love equation

$$\frac{\partial^4 w}{\partial x^4} + \frac{1}{D_0^4} \frac{\partial^2 w}{\partial t^2} - \left(\frac{1}{c_b^2} + \frac{1}{qc_t^2} \right) \frac{\partial^4 w}{\partial x^2 \partial t^2} = 0 \quad (1.17)$$

1.2.11 Timoshenko modified theory

Assumption

More arbitrary coefficients are entered into the basic equations.

The bending moment and shear in the most general case are

$$M_z = pEI_z \frac{\partial \psi}{\partial x}, \quad F_y = 2HG \left(q \frac{\partial w}{\partial x} + s\psi \right)$$

where p , q , and s are arbitrary coefficients.

Differential equation of transverse vibration

$$\frac{\partial^4 w}{\partial x^4} + \left(\frac{s}{pq} \right) \frac{1}{D_0^4} \frac{\partial^2 w}{\partial t^2} - \left(\frac{1}{pc_b^2} + \frac{1}{qc_t^2} \right) \frac{\partial^4 w}{\partial x^2 \partial t^2} + \frac{1}{pq c_b^2 c_t^2} \frac{\partial^4 w}{\partial t^4} = 0 \quad (1.18)$$

The dispersive equation may be written in the form

$$2k_{1,2}^2 = \frac{k_b^2}{p} + \frac{k_t^2}{q} \pm \sqrt{\left(\frac{k_b^2}{p} - \frac{k_t^2}{q} \right)^2 + 4k_0^4 \cdot \frac{s}{pq}}$$

The dispersive properties of the beam (and the corresponding dispersive curve) is sensitive to the change of parameters p , q and s . Two additional relationships between parameters p , q , s , such that

$$s = pq \quad \text{and} \quad k_t^2 \frac{I_z}{A} = pq$$

define a differential equation with one optimal correct multiplier. The meaning of the above-mentioned relationships was discussed by Artobolevsky *et al.* (1979). The special case $p = q$ was studied by Aalami and Atzori (1974).

Figure 1.4 presents the exact curves 1 and 2 and dispersive curves for different values of coefficient p : $p = 0.62$, $p = 0.72$, $p = \pi^2/12$, $p = 0.94$ and $p = 1$ (Timoshenko model). The best approximation is $p = \pi^2/12$ for $k_t H$ in the interval from 0 to π .

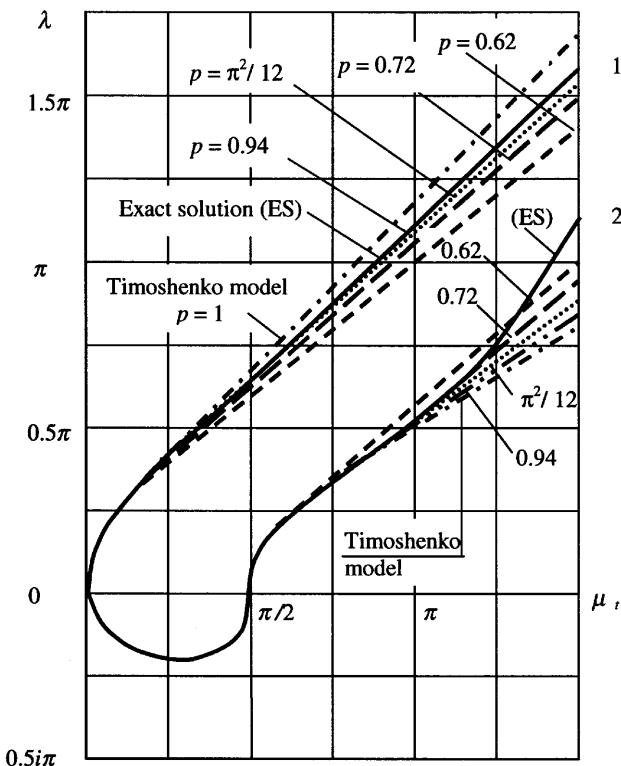

FIGURE 1.4. Dispersive curves for modified Timoshenko model. 1, 2—exact solution.

TRANSVERSE VIBRATION EQUATIONS

CHAPTER 2

ANALYSIS METHODS

Reciprocal theorems describe fundamental properties of elastic deformable systems. Displacement computation techniques are presented in this chapter, and the different calculation procedures for obtaining eigenvalues are discussed: among these are Lagrange's equations, Rayleigh, Rayleigh–Ritz and Bubnov–Galerkin's methods, Grammel, Dunkerley and Hohenemser–Prager's formulas, Bernstein and Smirnov's estimations.

a, b, c, d, e, f	Specific ordinates of the bending moment diagrams
a_{ik}	Inertial coefficients
c_{ik}	Elastic coefficients
E	Young's modulus of the beam material
EI	Bending stiffness
g	Gravitational acceleration
I_z	Moment of inertia of a cross-section
k	Stiffness coefficient
L, l, h, a, b	Geometrical parameters
M	Bending moment
m_{ij}, k_{ij}	Mass and stiffness coefficients
M, J	Concentrated mass and moment of inertia of the mass
n	Number of degrees of freedom
Q	Generalized force
q, \dot{q}, \ddot{q}	Generalized coordinate, generalized velocity and generalized acceleration
r	Radius of gyration
r_{ik}	Unit reaction
U, T	Potential and kinetic energy
x, y, z	Cartesian coordinates
$X(x)$	Mode shape
y_c	Ordinate of the bending moment diagram in the unit state under centroid of bending moment diagram in the actual state
δ_{ik}	Unit displacement
Ω	Area of the bending moment diagram under actual conditions

$(\cdot) = \frac{d}{dx}$	Differentiation with respect to space coordinate
$(\cdot) = \frac{d}{dt}$	Differentiation with respect to time

2.1 RECIPROCAL THEOREMS

Reciprocal theorems represent the fundamental and useful properties of arbitrary linear elastic systems. The fundamental investigations were developed by Betti (1872), Helmholtz (1860), Maxwell (1864) and Rayleigh (1873, 1876).

2.1.1 Theorem of reciprocal works (Betti, 1872)

The work performed by the actions of state 1 along the deflections caused by the actions corresponding to state 2 is equal to the work performed by the actions of state 2 along the deflections due to the actions of state 1, e.g. $A_{12} = A_{21}$.

2.1.2 Theorem of reciprocal displacements

If a harmonic force of given amplitude and period acts upon a system at point A , the resulting displacement at a second point B will be the same, both in amplitude and phase, as it would be at point A were the force to act at point B . The *statical reciprocal theorem* is the particular case in which the forces have an infinitely large period (Lord Rayleigh, 1873–1878).

Unit displacement δ_{ik} indicates the displacement along the i th direction (linear or angular) due to the unit load (force or moment) acting in the k th direction.

In any elastic system, the displacement along a load unity of state 1 caused by a load unity of state 2 is equal to the displacement along the load unity of state 2 caused by a load unity of the state 1, e.g. $\delta_{12} = \delta_{21}$.

Example. A simply supported beam carries a unit load P in the first condition and a unit moment M in the second condition (Fig. 2.1).

In the first state, the displacement due to load unity $P = 1$ along the load of state 2 is the angle of rotation

$$\theta = \delta_{21} = \frac{1 \times L^2}{24EI}$$

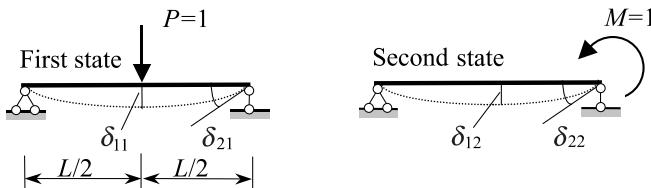

FIGURE 2.1. Theorem of reciprocal displacements.

In the second state, the displacement due to load unity $M = 1$ along the load of state 1 is a linear deflection

$$y = \delta_{12} = \frac{1 \times L^2}{24EI}$$

2.1.3 Theorem of the reciprocal of the reactions (Maxwell, 1864)

Unit reaction r_{ik} indicates the reaction (force or moment) induced in the i th support due to unit displacement (linear or angular) of the k th constraint.

The reactive force r_{nm} due to a unit displacement of constraint m along the direction n equals the reactive force r_{mn} induced by the unit displacement of constraint n along the direction m , e.g. $r_{nm} = r_{mn}$.

Example. Calculate the unit reactions for the frame given in Fig. 2.2a.

Solution. The solution method is the slope-deflection method. The given system has one rigid joint and allows one horizontal displacement. The primary system of the slope-deflection method is presented in Fig. 2.2(b). Restrictions 1 and 2 are additional ones that prevent angular and linear displacements. For a more detailed discussion of the slope-deflection method see Chapter 4.

State 1 presents the primary system under unit rotational angle $Z_1 = 1$ and the corresponding bending moment diagram; state 2 presents the primary system under unit horizontal displacement $Z_2 = 1$ and the corresponding bending moment diagram.

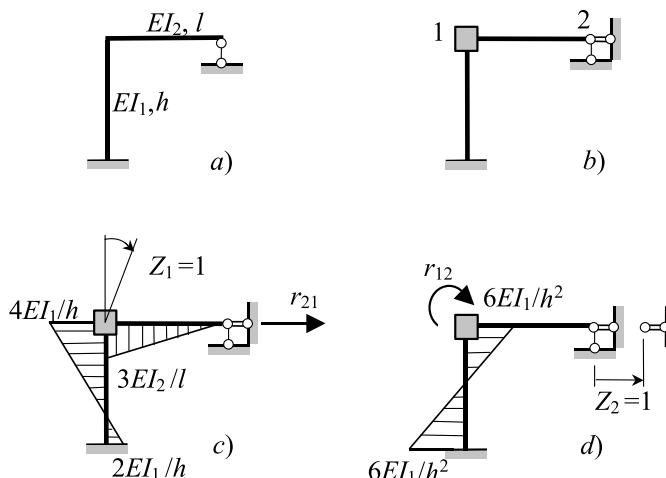

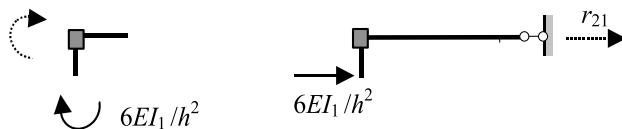

FIGURE 2.2. Theorem of the reciprocal of the reactions: (a) given system; (b) primary system of the slope and deflection method; (c) bending moment diagram due to unit angular displacement of restriction 1; (d) bending moment diagram due to unit linear displacement of restriction 2.

Free-body diagrams for joint 1 in state 2 using Fig. 2.2(d), and for the cross-bar in state 1 using Fig. 2.2(c) are presented as follows.

The equilibrium equation of the constraint 1 ($\Sigma M = 0$) leads to

$$r_{12} = -\frac{6EI_1}{h^2}$$

The equilibrium equation of the cross-bar 1–2 ($\Sigma F_x = 0$) leads to

$$r_{21} = -\frac{1}{h} \left(\frac{4EI_1}{h} + \frac{2EI_1}{h} \right) = -\frac{6EI_1}{h^2}$$

2.1.4 Theorem of the reciprocal of the displacements and reactions (Maxwell, 1864)

The displacement in the j th direction due to a unit displacement of the k th constraint and the reaction of the constraint k due to a unit force acting in the j th direction are equal in magnitude but opposite in sign, e.g. $\delta_{jk} = -r_{kj}$.

Example. Find a vertical displacement at the point A due to a unit rotation of support B (Fig. 2.3).

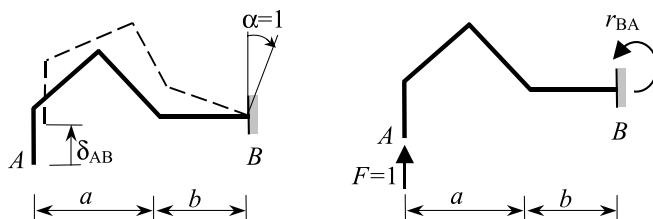

FIGURE 2.3. Theorem of the reciprocal of the displacements and reactions.

Solution. Let us apply the unit force $F = 1$ in the direction δ_{AB} . The moment at the fixed support due to force $F = 1$ equals $r_{BA} = -F(a + b)$.

Since $F = 1$, the vertical displacement $\delta_{AB} = a + b$.

2.2 DISPLACEMENT COMPUTATION TECHNIQUES

2.2.1 Maxwell-Morh integral

Any displacement of the linear deformable system may be calculated by the formula

$$\Delta_{ik} = \sum \int_0^l \frac{M_i M_k}{EI} dx + \sum \int_0^l \frac{N_i N_k}{EA} dx + \sum \int_0^l \frac{Q_i Q_k}{GA} \eta dx \quad (2.1)$$

where $M_k(x)$, $N_k(x)$ and $Q_k(x)$ represent the bending moment, axial and shear forces acting over a cross-section situated a distance x from the coordinate origin; these internal forces are due to the applied loads;

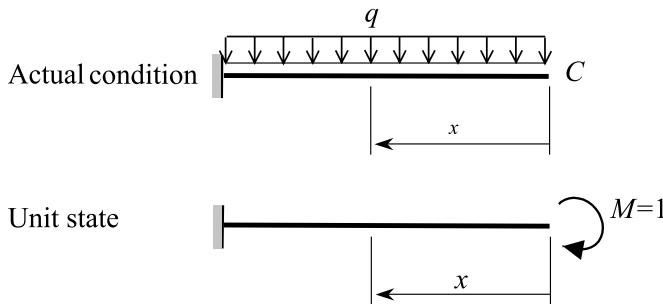

$M_i(x)$, $N_i(x)$ and $Q_i(x)$ represent the bending moment, axial and shear forces due to a unit load that corresponds to the displacement Δ_{ik} ;

η is the non-dimensional shear factor that depends on the shape and size of the cross-section. Detailed information about the shear factor is presented in Chapter 1.

For bending systems, the second and third terms may be neglected.

Example. Compute the angle of rotation of end point C of a uniformly loaded cantilever beam.

Solution. The unit state—or the imaginary one—is a cantilever beam with a unit moment that is applied at the point C; this moment corresponds to an unknown angle of rotation at the same point C.

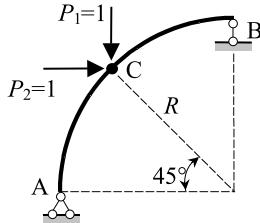

The bending moments in the actual condition M_k and the unit state M_i are

$$M_k(x) = \frac{qx^2}{2}, \quad M_i = 1 \times x$$

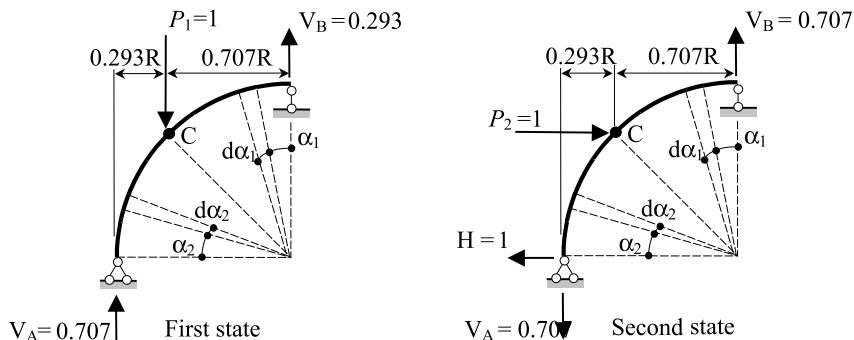

The angle of rotation

$$\Delta_{ik} = \sum \int_0^l \frac{M_i M_k}{EI} dx = \int_0^l \frac{1 \times x \times qx^2}{2EI} dx = \frac{q l^3}{6EI}$$

Example. Compute the vertical and horizontal displacements at the point C of a uniformly circular pinned-roller supported arch, due to unit loads $P_1 = 1$ and $P_2 = 1$.

Solution. The first state is the arch with a unit vertical load that is applied at point C; the second state is the arch with a unit horizontal load, which is applied at the same point.

The unit displacements according to the first term of equation (2.1) are (Prokofiev *et al.*, 1948)

$$\begin{aligned}\delta_{11} &= \int_0^{\pi/4} \frac{1}{EI} (0.293R \sin \alpha_1)^2 R d\alpha_1 + \int_0^{\pi/4} \frac{1}{EI} [0.707(1 - \cos \alpha_2)R]^2 R d\alpha_2 = \frac{0.01925R^3}{EI} \\ \delta_{22} &= \int_0^{\pi/4} \frac{1}{EI} (0.707R \sin \alpha_1)^2 R d\alpha_1 + \int_0^{\pi/4} \frac{1}{EI} [R \sin \alpha_2 - 0.707R(1 - \cos \alpha_2)]^2 R d\alpha_2 = \frac{0.1604R^3}{EI} \\ \delta_{12} = \delta_{21} &= \int_0^{\pi/4} \frac{1}{EI} 0.707 \times 0.293R^3 \sin^2 \alpha_1 d\alpha_1 \\ &+ \int_0^{\pi/4} \frac{1}{EI} [R \sin \alpha_2 - 0.707R(1 - \cos \alpha_2)] \times 0.707R(1 - \cos \alpha_2)R d\alpha_2 = 0.0530 \frac{R^3}{EI}\end{aligned}$$

Graph multiplication method (Vereshchagin method). In the most common case, the bending moment diagram is the actual condition bounded by any curve. The bending moment diagram that corresponds to the unit condition is always bounded by a straight line. This latter property allows us to present the Maxwell–Morph integral for bending systems (Vereshchagin, 1925; Flugge, 1962; Darkov, 1989).

$$\frac{1}{EI} \int M_i M_k dx = \frac{1}{EI} Q y_c \quad (2.2)$$

The product of the multiplication of two graphs, at least one of which is bounded by a straight line, equals the area Ω bounded by the graph of an arbitrary outline multiplied by the ordinate y_c to the first graph measured along the vertical passing through the centroid of the second one. The ordinate y_c must be measured on the graph bounded by a straight line (Fig. 2.4).

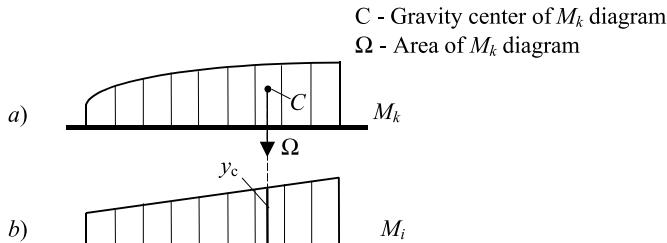

FIGURE 2.4. Graph multiplication method: (a) bending moment diagram that corresponds to the actual condition; (b) bending moment diagram that corresponds to the unit condition.

If a bending structure in the actual condition is under concentrated forces and/or moments, then both of bending moment diagrams in actual and unit conditions are bounded by straight lines (Fig. 2.4). In this case, the ordinate y_c could be measured on either of the two lines.

If both graphs are bounded by straight lines, then expression (2.2) may be presented in terms of specific ordinates, as presented in Fig. 2.5. In this case, displacement as a result of the multiplication of two graphs may be calculated by the following expressions.

Exact formula

$$\delta_{ik} = \frac{l}{6EI} (2ab + 2cd + ad + bc) \quad (2.3)$$

Approximate formula (Simpson-Kornoukhov's rule)

$$\delta_{ik} = \frac{l}{6EI} (ab + cd + 4ef) \quad (2.4)$$

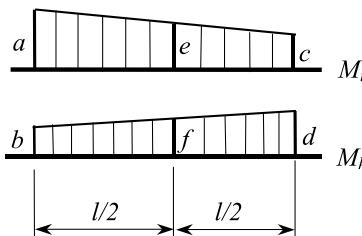

FIGURE 2.5. Bending moment diagrams bounded by straight lines.

Equation (2.3) is used if two bending moment graphs are bounded by straight lines only. Equation (2.4) may be used for the calculation of displacements if the bending moment diagram in the actual condition is bounded by a curved line. If the bending moment diagram in the actual condition is bounded by the quadratic parabola, then the result of the multiplication of two bending moment diagrams is exact. This case occurs if the bending structure is carrying a uniformly distributed load.

Unit displacement is displacement due to a unit force or unit moment and may be calculated by expressions (2.3) or (2.4).

Example. A cantilever beam is carrying a uniformly distributed load q . Calculate the vertical displacement at the free end.

Solution. The bending moment diagram due to the applied uniformly distributed force (M_q), unit condition and corresponding bending moment diagram $M_{P=1}$ are presented in Fig. 2.6.

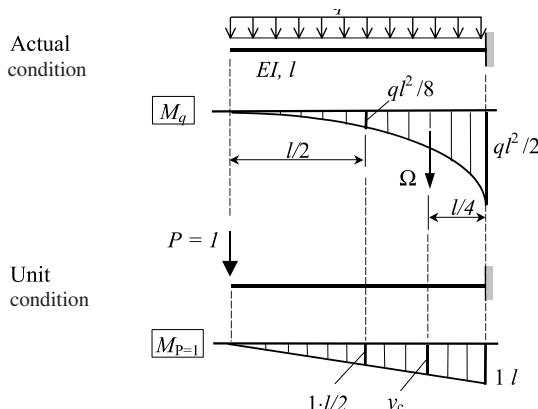

FIGURE 2.6. Actual state, unit condition and corresponding bending moment diagram.

The bending moment diagram in the actual condition is bounded by the quadratic parabola. The vertical displacement at the free end, by using the exact and approximate formulae, respectively, is

$$\Delta = \frac{1}{EI} \times \underbrace{\frac{1}{3}l \times \frac{ql^2}{2}}_{\Omega} \times \underbrace{\frac{3}{4}1 \times l}_{y_c} = \frac{ql^4}{8EI}$$

$$\Delta = \frac{l}{6EI} \left(\underbrace{0 \times 0}_{ab} + \underbrace{\frac{ql^2}{2} \times 1 \times l}_{cd} + 4 \times \underbrace{\frac{ql^2}{8} \times 1 \frac{l}{2}}_{4ef} \right) = \frac{ql^4}{8EI}$$

Example. Consider the portal frame shown in Fig. 2.7. Calculate the horizontal displacement of the point B .

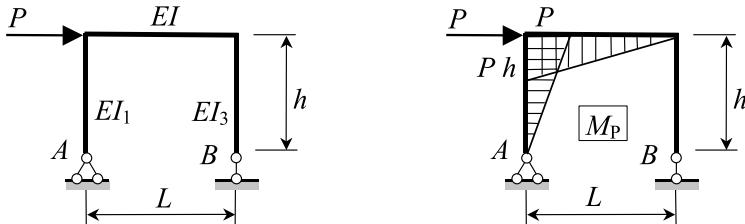

FIGURE 2.7. Portal frame: actual condition and corresponding bending moment diagram.

Solution. The bending moment diagram, M_p , corresponding to the actual loading, P , is presented in Fig. 2.7.

The unit loading consists of one horizontal load of unity acting at point B . The corresponding bending moment diagram M_i is given in Fig. 2.8.

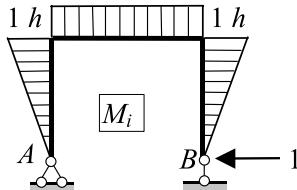

FIGURE 2.8. Unit condition and corresponding bending moment diagram.

The signs of the bending moment appearing in these graphs may be omitted if desired, as these graphs are always drawn on the side of the tensile fibres. The displacement of the point B will be obtained by multiplying the two bending moment diagrams. Using Vereshchagin's method and taking into account the different rigidities of the columns and of the cross beam, we find

$$\Delta_B = -\frac{1}{EI_1} \times \underbrace{\frac{1}{2}h \times Ph \times \underbrace{\frac{2}{3}h}_{y_c}}_{\Omega} - \frac{1}{EI_2} \times \underbrace{\frac{1}{2}Ph \times L \times \underbrace{h}_{y_c}}_{\Omega} = -\frac{Ph^3}{3EI_1} - \frac{PLh^2}{2EI_2}$$

2.2.2 Displacement in indeterminate structures

The deflections of a redundant structure may be determined by using only one bending moment diagram pertaining to the given structure—either that induced by the applied loads or else that due to a load unity acting along the desired deflection. The second graph may be traced for *any* simple structure derived from the given structure by the elimination of redundant constraints.

Example. Calculate the angle of displacement of the point B of the frame shown in Fig. 2.9. The stiffnesses of all members are equal, and $L = h$.

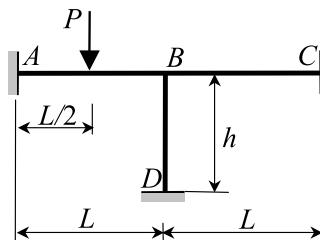

FIGURE 2.9. Design diagram of the statically indeterminate structure.

Solution. The bending moment diagram in the actual condition and the corresponding bending moment diagram in the unit condition are presented in Fig. 2.10.

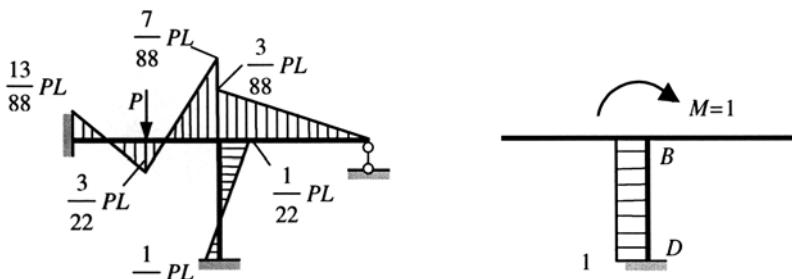

FIGURE 2.10. Bending moment diagrams in the actual and unit conditions.

The angular displacement may be calculated by using Equation 2.3

$$\theta_B = \frac{h}{6EI} \left(-2 \times 1 \times \frac{PL}{22} + 2 \times 1 \times \frac{PL}{44} + 1 \times \frac{PL}{44} - 1 \times \frac{PL}{22} \right) = -\frac{PL^2}{88EI}$$

2.2.3 Influence coefficients

Influence coefficients (unit displacements) δ_{ik} are the displacement in the i th direction caused by unit force acting in the k th direction (see Tables 2.1 and 2.2).

In Table 2.2 the influence coefficients at point 1 due to a unit force or moment being applied at the same point 1 are:

δ = vertical displacement due to unit vertical force;

β = angle of rotation due to unit vertical force or vertical displacement due to unit moment;

γ = angle of rotation due to unit moment.

Example. Calculate the matrix of the unit displacements for the symmetric beam shown in Fig. 2.11

TABLE 2.1 Influence coefficients for beams with classical boundary conditions (static Green functions); $EI = \text{const}$.

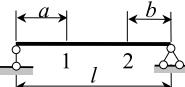

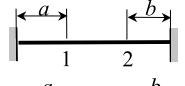

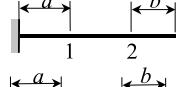

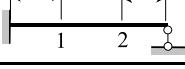

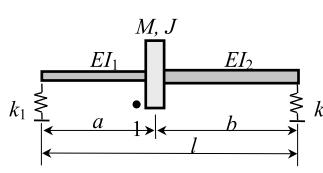

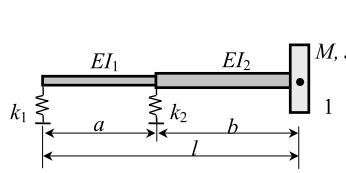

Beam type	δ_{11}	$\delta_{12} = \delta_{21}$	δ_{22}
	$\frac{l^3}{3EI} \left(\frac{l-a}{l} \right)^2 \left(\frac{a}{l} \right)^2$	$\frac{ab(l^2 - a^2 - b^2)}{6EI}$	$\frac{l^3}{3EI} \frac{(l-a)^2}{l^2} \left(\frac{b}{l} \right)^2$
	$\frac{a^3(l-a)^3}{3l^3EI}$	$\frac{a^2b^2}{2l^2EI} \left(l - a - b + \frac{2ab}{3} \right)$	$\frac{b^2(l-b)^2}{3l^3EI}$
	$\frac{a^3}{3EI}$	$\frac{a^2}{2EI} \left(l - b - \frac{a}{3} \right)$	$\frac{(l-b)^3}{3EI}$
	$\frac{(l-a)^2a^3}{12l^2EI} \left(4 - \frac{a}{l} \right)$	$\frac{a^2b}{12lEI} \left[3(l-a) \frac{b^2}{l^2} (3l-a) \right]$	$\frac{b^2(l-b)^3}{12l^2EI} \left(3 + \frac{b}{l} \right)$

TABLE 2.2 Influence coefficients for beams with non-classical boundary conditions; $EI = \text{const}$.

Beam type	Influence coefficients
	$\delta = \frac{a^2k_2 + b^2k_1 + a^3b^3}{l^2} + \frac{a^3b^3}{3l^2EI_1} + \frac{a^2b^3}{3l^2EI_2}$ $\beta = \frac{bk_1 - ak_2}{l^2} + \frac{a^3b}{3l^2EI_1} - \frac{ab^3}{3l^2EI_2}$ $\gamma = \frac{k_1 + k_2}{l^2} + \frac{a^3}{3l^2EI_1} + \frac{b^3}{3l^2EI_2}$
	$\delta = \frac{b^2k_1 + (a+b)^2k_2}{a^2} + \frac{ab^2}{3EI_1} + \frac{b^3}{3EI_2}$ $\beta = \frac{bk_1 + (a+b)k_2}{a^2} + \frac{ab}{3EI_1} + \frac{b^2}{3EI_2}$ $\gamma = \frac{k_2 + k_1}{a^2} + \frac{a}{3EI_1} + \frac{b}{3EI_2}$

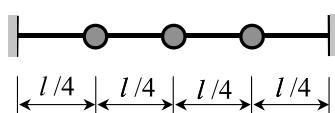

FIGURE 2.11. Clamped-clamped beam with lumped masses.

Solution. By using Table 2.1, case 2, the symmetric matrix of the unit displacements is

$$[\delta_{ik}] = \frac{l^3}{EI} \begin{vmatrix} \frac{9}{4096} & \frac{1}{384} & \frac{13}{12288} \\ & \frac{1}{192} & \frac{1}{384} \\ & & \frac{9}{4096} \end{vmatrix}$$

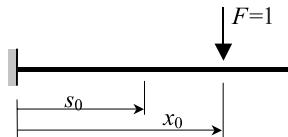

2.2.4 Influence coefficients for clamped-free beam of non-uniform cross-sectional area

The distributed mass and the second moment of inertia

$$m(x) = m_0 \left[1 - \left(1 - \frac{m_1}{m_0} \right) \frac{x}{l} \right], \quad EI(x) = EI_0 \left(1 - \frac{x}{l} \right)^n \quad (2.5)$$

where m_0, I_0 are mass per unit length and moment of inertia at clamped support ($x = 0$),
 m_1 is mass per unit length at free end ($x = l$),
 n is any integer or decimal number.

The unit force applied at $x = x_0$ and the position of any section $x = s_0$, are as shown.

The influence coefficient (Green's function, see also Section 3.10) satisfies the Maxwell theorem, or the symmetry property

$$G(x, s) = G(s, x)$$

and may be presented in the form (Anan'ev, 1946)

$$G(x, s) = \frac{l^3}{(1-n)(2-n)EI_0} \times \begin{cases} (1-s)^{2-n}(x-s) + (2-n)xs - x - s - \frac{2}{3-n}(1-s)^{3-n} + \frac{2}{3-n} & \text{for } x \geq s \\ (1-x)^{2-n}(s-x) + (2-n)sx - s - x - \frac{2}{3-n}(1-x)^{3-n} + \frac{2}{3-n} & \text{for } x < s \end{cases} \quad (2.6)$$

$$G(x, s) = \frac{l^3}{(1-n)(2-n)EI_0} \times \begin{cases} (1-x)^{2-n}(s-x) + (2-n)sx - s - x - \frac{2}{3-n}(1-x)^{3-n} + \frac{2}{3-n} & \text{for } x < s \\ (1-s)^{2-n}(x-s) + (2-n)xs - x - s - \frac{2}{3-n}(1-s)^{3-n} + \frac{2}{3-n} & \text{for } x \geq s \end{cases} \quad (2.7)$$

where $x = \frac{x_0}{l}$, $s = \frac{s_0}{l}$ are non-dimensional parameters.

Expressions (2.6) and (2.7) have no singular points except $n = 1, n = 2$ and $n = 3$. For $n > 2, s \neq 1, x \neq 1$.

Special case. For a uniform cross-sectional area, the parameter $n = 0$, which yields the result presented in Table 2.1, row 3.

2.3 ANALYSIS METHODS

2.3.1 Lagrange's equation

Lagrange's equation offers a uniform and fairly simple method for the formulation of the vibration equations of a mechanical system

$$\frac{d}{dt} \left(\frac{\partial T}{\partial \dot{q}_i} \right) - \frac{\partial T}{\partial q_i} + \frac{\partial U}{\partial q_i} = Q_i, \quad i = 1, 2, 3, \dots, n \quad (2.8)$$

where T and U are the kinetic energy and potential energy of the system;

q_i and \dot{q}_i are generalized coordinates and generalized velocities;

t is time;

Q_i is generalized force, which corresponds to generalized coordinate q_i ;

n is number of degrees of freedom of the system.

The generalized force Q_i , which corresponds to the generalized coordinate q_i is equal to the coefficient at increment of generalized coordinate in the expression for virtual work. In the case of ideal constraints, the right-hand parts of Lagrange's equation include only generalized active forces, and the unknown reactions of the constraints need not be considered. An important advantage is that their form and number depend neither on the number of bodies comprising the system nor on the manner in which they are moving. The number of equations equals the number of degrees of freedom of the system.

The kinetic energy of the system is a quadratic function of the generalized velocities

$$T = \frac{1}{2} \sum_{i,k=1}^n a_{ik} \dot{q}_i \dot{q}_k \quad (i, k = 1, 2, \dots, n) \quad (2.9)$$

Inertial coefficients satisfy the reciprocal property, $a_{ik} = a_{ki}$.

The potential energy of the system is a quadratic function of the generalized coordinates

$$U = \frac{1}{2} \sum_{i,k=1}^n c_{ik} q_i q_k \quad (i, k = 1, 2, \dots, n) \quad (2.10)$$

The elastic coefficients satisfy the reciprocal property, $c_{ik} = c_{ki}$.

The differential equations of mechanical system are

$$\begin{aligned} a_{11}\ddot{q}_1 + a_{12}\ddot{q}_2 + \cdots + a_{1n}\ddot{q}_n &= -c_{11}q_1 - c_{12}q_2 - \cdots - c_{1n}q_n \\ a_{21}\ddot{q}_1 + a_{22}\ddot{q}_2 + \cdots + a_{2n}\ddot{q}_n &= -c_{21}q_1 - c_{22}q_2 - \cdots - c_{2n}q_n \\ \dots &\\ a_{n1}\ddot{q}_1 + a_{n2}\ddot{q}_2 + \cdots + a_{nn}\ddot{q}_n &= -c_{n1}q_1 - c_{n2}q_2 - \cdots - c_{nn}q_n \end{aligned} \quad (2.11)$$

Lagrange's equations can be used in the dynamic analysis of structures with complex geometrical shapes and complex boundary conditions.

The system of differential equations (2.11) has the following solution

$$q_i = A_i \exp i\omega t \quad (2.12)$$

where A_i is amplitude and ω is the frequency of vibration.

By substituting Equations (2.12) into system (2.11), and reducing by $\exp i\omega t$, we obtain a homogeneous algebraic equation with respect to unknown amplitudes. The condition of non-trivial solution leads to the frequency equation

$$\begin{vmatrix} a_{11}\omega^2 - c_{11} & a_{12}\omega^2 - c_{12} & \cdots & a_{1n}\omega^2 - c_{1n} \\ a_{21}\omega^2 - c_{21} & a_{22}\omega^2 - c_{22} & \cdots & a_{2n}\omega^2 - c_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ a_{n1}\omega^2 - c_{n1} & a_{n2}\omega^2 - c_{n2} & \cdots & a_{nn}\omega^2 - c_{nn} \end{vmatrix} = 0 \quad (2.13)$$

All roots of the frequency equation ω^2 are real and positive.

The special forms of kinetic or potential energy lead to specific forms for the frequency equation.

Direct form. Kinetic energy is presented as sum of squares of generalized velocities

$$\begin{aligned} T &= \frac{1}{2} \sum_{k=1}^n a_k \dot{q}_k^2 \\ U &= \frac{1}{2} \sum_{i,k=1}^n c_{ik} q_i q_k \quad (i, k = 1, 2, \dots, n) \end{aligned} \quad (2.14)$$

In this case, the differential equations of the mechanical system are solved with respect to generalized accelerations

$$\begin{aligned} a_1 \ddot{q}_1 &= -c_{11}q_1 - c_{12}q_2 - \cdots - c_{1n}q_n \\ a_2 \ddot{q}_2 &= -c_{21}q_1 - c_{22}q_2 - \cdots - c_{2n}q_n \\ \cdots &\cdots \\ a_n \ddot{q}_n &= -c_{n1}q_1 - c_{n2}q_2 - \cdots - c_{nn}q_n \end{aligned}$$

Presenting the generalized coordinates in the form of Equation (2.12), and using the non-triviality condition, leads to the frequency equation

$$\begin{vmatrix} m_1\omega^2 - r_{11} & -r_{12} & \cdots & -r_{1n} \\ -r_{21} & m_2\omega^2 - r_{22} & \cdots & -r_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ -r_{n1} & -r_{n2} & \cdots & m_n\omega^2 - r_{nn} \end{vmatrix} = 0 \quad (2.15)$$

where r_{ik} are unit reactions (force or moment) in the i th restriction, which prevents linear or angular displacement due to unit displacement (linear or angular) of the k th restriction. The unit reactions satisfy the property of reciprocal reactions, $r_{ik} = r_{ki}$ (the *theorem of reciprocal reactions*).

Inverted form. Potential energy is presented as sum of squares of generalized coordinates

$$\begin{aligned} T &= \frac{1}{2} \sum_{i,k=1}^n a_{ik} \dot{q}_i \dot{q}_k \quad (i, k = 1, 2, \dots, n) \\ U &= \frac{1}{2} \sum_{k=1}^n c_k q_k^2 \quad (i, k = 1, 2, \dots, n) \end{aligned} \quad (2.16)$$

The differential equations of a mechanical system solved with respect to generalized coordinates are

$$\begin{aligned} c_1 q_1 &= -a_{11}\ddot{q}_1 - a_{12}\ddot{q}_2 - \cdots - a_{1n}\ddot{q}_n \\ c_2 q_2 &= -a_{21}\ddot{q}_1 - a_{22}\ddot{q}_2 - \cdots - a_{2n}\ddot{q}_n \\ &\dots \\ c_n q_n &= -a_{n1}\ddot{q}_1 - a_{n2}\ddot{q}_2 - \cdots - a_{nn}\ddot{q}_n \end{aligned}$$

Solution of these system in the form of Equation (2.12), and using the non-triviality condition, leads to the frequency equation in terms of coefficients a and c

$$\begin{vmatrix} c_1 - a_{11}\omega^2 & -a_{12}\omega^2 & \cdots & -a_{1n}\omega^2 \\ -a_{21}\omega^2 & c_2 - a_{22}\omega^2 & \cdots & -a_{2n}\omega^2 \\ \cdots & \cdots & \cdots & \cdots \\ -a_{n1}\omega^2 & -a_{n2}\omega^2 & \cdots & c_n - a_{nn}\omega^2 \end{vmatrix} = 0 \quad (2.17)$$

In terms of lumped masses m and unit displacements δ_{ik} the frequency equation becomes

$$\begin{vmatrix} 1 - m_1\delta_{11}\omega^2 & -m_2\delta_{12}\omega^2 & \cdots & -m_n\delta_{1n}\omega^2 \\ -m_1\delta_{21}\omega^2 & 1 - m_2\delta_{22}\omega^2 & \cdots & -m_n\delta_{2n}\omega^2 \\ \cdots & \cdots & \cdots & \cdots \\ -m_1\delta_{n1}\omega^2 & -m_2\delta_{n2}\omega^2 & \cdots & 1 - m_n\delta_{nn}\omega^2 \end{vmatrix} = 0 \quad (2.18)$$

where δ_{ik} is displacement in the i th direction due to the unit inertial load which is acting in the k th direction. The unit displacements satisfy the property of reciprocal displacements $\delta_{ik} = \delta_{ki}$ (the *theorem of reciprocal displacements*).

Example. Using Lagrange's equation, derive the differential equation of motion of the system shown in Fig. 2.12.

Solution. The system has two degrees of freedom. Generalized coordinates are $q_1 = x_1$ and $q_2 = x_2$. Lagrange's equation must be re-written as

$$\begin{aligned} \frac{d}{dt} \left(\frac{\partial T}{\partial \dot{q}_1} \right) - \frac{\partial T}{\partial q_1} &= Q_1 \\ \frac{d}{dt} \left(\frac{\partial T}{\partial \dot{q}_2} \right) - \frac{\partial T}{\partial q_2} &= Q_2 \end{aligned}$$

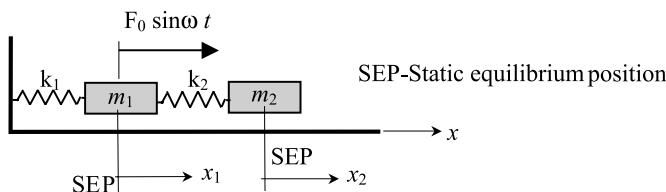

FIGURE 2.12. Mechanical system with two degrees of freedom.

where Q_1 and Q_2 are the generalized forces associated with generalized coordinates x_1 and x_2 , of the system, respectively.

The kinetic energy, T , of the system is equal to the sum of kinetic energies of the masses m_1 and m_2

$$T = \frac{1}{2}m_1\dot{x}_1^2 + \frac{1}{2}m_2\dot{x}_2^2$$

so kinetic energy, T , depends only on the generalized velocities, and not on generalized coordinates. By using the definition of the kinetic energy, one obtains

$$\begin{aligned}\frac{\partial T}{\partial \dot{x}_1} &= m_1\dot{x}_1 & \frac{d}{dt}\left(\frac{\partial T}{\partial \dot{x}_1}\right) &= m_1\ddot{x}_1 & \frac{\partial T}{\partial x_1} &= 0 \\ \frac{\partial T}{\partial \dot{x}_2} &= m_2\dot{x}_2 & \frac{d}{dt}\left(\frac{\partial T}{\partial \dot{x}_2}\right) &= m_2\ddot{x}_2 & \frac{\partial T}{\partial x_2} &= 0\end{aligned}$$

For calculation of Q_1 and Q_2 we need to show all forces that act on the masses m_1 and m_2 at positions x_1 and x_2 (Fig. 2.13).

The total elementary work δW , which could have been done on the increments of the generalized coordinates δx_1 and δx_2 , is

$$\delta W = Q_1\delta q_1 + Q_2\delta q_2 = \delta x_1[-k_1x_1 - k_2(x_1 - x_2) + F_0 \sin \omega t] + \delta x_2k_2(x_1 - x_2)$$

The coefficient at δx_1 is the generalized force Q_1 , and the coefficient at δx_2 is the generalized force Q_2 .

So, generalized forces are

$$\begin{aligned}Q_1 &= -k_1x_1 - k_2(x_1 - x_2) + F_0 \sin \omega t \\ Q_2 &= k_2(x_1 - x_2)\end{aligned}$$

Substituting into Lagrange's equation for q_1 and q_2 yields, respectively, the following two differential equations

$$\begin{aligned}m_1\ddot{x}_1 + (k_1 + k_2)x_1 - k_2x_2 &= F_0 \sin \omega t \\ m_2\ddot{x}_2 - k_2x_1 + k_2x_2 &= 0\end{aligned}$$

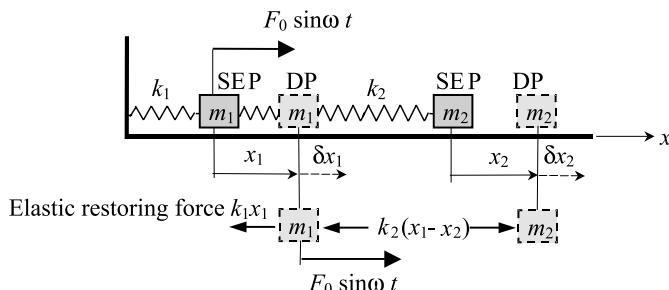

FIGURE 2.13. Real displacements x_1 , x_2 and virtual displacements δx_1 , δx_2 . SEP = Static equilibrium position; DP = Displaced position.

These equations describe forced vibration. The solution of this differential equation system and its technical applications are discussed in detail by Den Hartog (1968), Weaver *et al.* (1990).

Example. Using the direct form, derive the frequency equation of the system shown in Fig. 2.14.

Solution

- Let mass m_1 have unit displacement in the positive direction while mass m_2 is fixed (Fig. 2.15(a)). The elastic restoring forces acting on mass m_1 are $F_1 = k_1$ from the left side and $F_2 = k_2$ from the right side; the restoring force acting on mass m_2 is $F_2 = k_2$. Reactions that act on masses m_1 and m_2 are r_{11} and r_{21} , respectively. The dotted reactions are shown in the positive direction. The equilibrium equation for mass m_1 and mass m_2 is $\Sigma F_{kx} = 0$, which leads to

$$r_{11} = k_1 + k_2 \quad \text{and} \quad r_{21} = -k_2$$

- Let mass m_2 have unit displacement in the positive direction; mass m_1 is fixed (Fig. 2.15(b)). The elastic restoring force acting on mass m_1 is $F_1 = k_2$ from the right side; the restoring force acting on mass m_2 is $F_2 = k_2$. The reactions that act on masses m_1

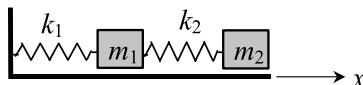

FIGURE 2.14. Mechanical system with two degrees of freedom.

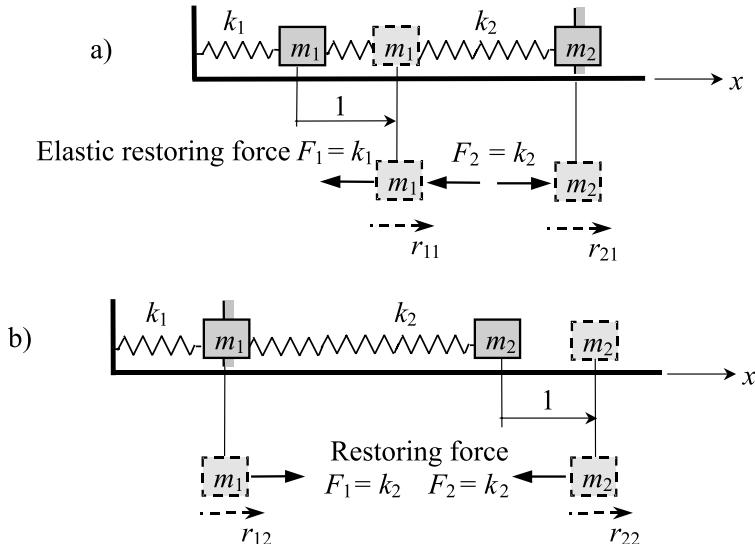

FIGURE 2.15. (a) Calculation of coefficients r_{11} and r_{21} . Direct form. (b) Calculation of coefficients r_{12} and r_{22} . Direct form.

and m_2 are r_{12} and r_{22} , respectively. The equilibrium equation for mass m_1 and mass m_2 is $\Sigma F_{kx} = 0$, which leads to

$$r_{12} = -k_2 \quad \text{and} \quad r_{22} = k_2$$

The frequency equation corresponding to the direct form (2.15) may be formed immediately

$$D = \begin{vmatrix} m_1\omega^2 - k_1 - k_2 & k_2 \\ k_2 & m_2\omega^2 - k_2 \end{vmatrix} = 0$$

Example. Using the inverted form, derive the frequency equation of the system shown in Fig. 2.14.

Solution

- Let unit force $F = 1$ be applied to mass m_1 in the positive direction while mass m_2 has no additional restriction (Fig. 2.16(a)). In this case, displacement of the mass m_1 is $\delta_{11} = 1/k_1$; the displacement mass m_2 equals δ_{11} , since mass m_2 has no restriction.
- Let unit force $F = 1$ be applied to mass m_2 in the positive direction. Thus mass m_2 is under action of active force, while mass m_1 has no active force applied to it (Fig. 2.16(b)). In this case, the internal forces in both springs are equal, $F = 1$.

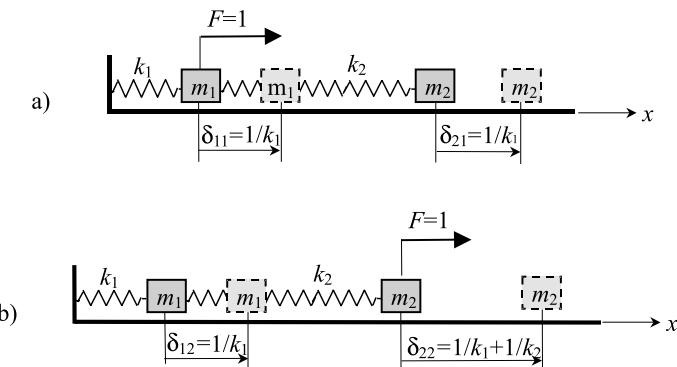

FIGURE 2.16. (a) Calculation of coefficients δ_{11} and δ_{21} . (b) Calculation of coefficients δ_{12} and δ_{22} . Inverted form.

The frequency equation may be formed immediately

$$D = \begin{vmatrix} 1 - \frac{m_1}{k_1}\omega^2 & -\frac{m_2}{k_1}\omega^2 \\ -\frac{m_1}{k_1}\omega^2 & 1 - m_2\omega^2\left(\frac{1}{k_1} + \frac{1}{k_2}\right) \end{vmatrix} = 0$$

The frequency equations in the direct and inverted forms are equivalent.

Example. The system shown in Fig. 2.17 consists of a clamped-free beam and a rigid body of mass M and radius of gyration r with respect to centroid C . Derive the frequency equation.

Solution. Generalized coordinates are the vertical displacement $q_1 = f$ at the point A and angular displacement $q_2 = \varphi$ at the same point. The corresponding generalized forces are concentrated force P_0 and moment M_0 , which are applied at point A .

The kinetic energy of the system is

$$T = \frac{1}{2} M \left[(\dot{f} + d\dot{\varphi})^2 + r^2 \dot{\varphi}^2 \right] = \frac{1}{2} M \left[\dot{f}^2 + (d^2 + r^2) \dot{\varphi}^2 + 2d\dot{f}\dot{\varphi} \right]$$

Kinetic energy may be presented in the canonical form (2.16)

$$T = \frac{1}{2} (a_{11}\dot{q}_1^2 + 2a_{12}\dot{q}_1\dot{q}_2 + a_{22}\dot{q}_2^2)$$

where a_{ik} are inertial coefficients.

Differential equations of motion in the inverted form are presented by Loitzjansky and Lur'e (1934)

$$\begin{aligned} f &= -\delta_{ff}(a_{11}\ddot{f} + a_{12}\ddot{\varphi}) - \delta_{f\varphi}(a_{12}\ddot{f} + a_{22}\ddot{\varphi}) \\ &= -\delta_{ff}(M\ddot{f} + Md\ddot{\varphi}) - \delta_{f\varphi}[Md\ddot{f} + M(r^2 + d^2)\ddot{\varphi}] \\ \varphi &= -\delta_{\varphi f}(a_{11}\ddot{f} + a_{12}\ddot{\varphi}) - \delta_{\varphi\varphi}(a_{12}\ddot{f} + a_{22}\ddot{\varphi}) \\ &= -\delta_{\varphi f}(M\ddot{f} + Md\ddot{\varphi}) - \delta_{\varphi\varphi}[Md\ddot{f} + M(r^2 + d^2)\ddot{\varphi}] \end{aligned}$$

where δ_{ff} , $\delta_{f\varphi}$, $\delta_{\varphi f}$, $\delta_{\varphi\varphi}$ are the influence coefficients.

Calculation of influence coefficients. Bending moment due to generalized forces

$$M(x) = P_0x + M_0$$

Potential energy

$$U = \frac{1}{2} \int_0^l \frac{M^2(x)}{EI} dx = \frac{1}{2} \left[P_0^2 \frac{l^3}{3} + 2P_0M_0 \frac{l^2}{2} + M_0^2 l \right]$$

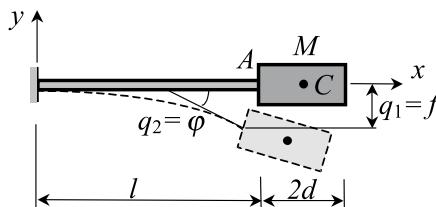

FIGURE 2.17. Cantilever beam with a rigid body at the free end.

By using the Castigiano theorem

$$f = \frac{\partial U}{\partial P_0} = \frac{l^3}{3EI} P_0 + \frac{l^2}{2EI} M_0$$

$$\varphi = \frac{\partial U}{\partial M_0} = \frac{l^2}{2EI} P_0 + \frac{l}{EI} M_0$$

So, the influence coefficients are

$$\delta_{ff} = \frac{l^3}{3EI}, \quad \delta_{\varphi f} = \delta_{f\varphi} = \frac{l^2}{2EI}, \quad \delta_{\varphi\varphi} = \frac{l}{EI}$$

The influence coefficients may be obtained from Table 2.1 immediately.

If the generalized coordinates change by the harmonic law, then the equations with respect to f and φ lead to the frequency equation

$$\begin{vmatrix} 1 - l_{ff}\omega^2 & -l_{f\varphi}\omega^2 \\ -l_{\varphi f}\omega^2 & 1 - l_{\varphi\varphi}\omega^2 \end{vmatrix} = 0$$

where

$$\begin{aligned} l_{ff} &= \delta_{ff}a_{11} + \delta_{f\varphi}a_{12} & l_{f\varphi} &= \delta_{ff}a_{12} + \delta_{f\varphi}a_{22} \\ l_{\varphi f} &= \delta_{f\varphi}a_{11} + \delta_{\varphi\varphi}a_{12} & l_{\varphi\varphi} &= \delta_{f\varphi}a_{12} + \delta_{\varphi\varphi}a_{22} \end{aligned}$$

The parameters l in the explicit form are

$$\begin{aligned} l_{ff} &= \frac{l^3 M}{3EI} \left(1 + \frac{3d}{2l} \right); & l_{f\varphi} &= \frac{l^3 M}{3EI} \left(d + \frac{3}{2} \frac{d^2 + r^2}{l} \right) \\ l_{\varphi f} &= \frac{l^3 M}{EI} \left(\frac{1}{2l} + \frac{d}{l^2} \right); & l_{\varphi\varphi} &= \frac{l^3 M}{EI} \left(\frac{d}{2l} + \frac{d^2 + r^2}{l^2} \right) \end{aligned}$$

The roots of equation $D = 0$

$$\Omega_{1,2}^2 = \frac{1}{2} \left\{ 1 + \frac{3d}{l} + \frac{3(d^2 + r^2)}{l^2} \pm \sqrt{\left[1 + \frac{3d}{l} + \frac{3(d^2 + r^2)}{l^2} \right]^2 - \frac{3r^2}{l^2}} \right\}$$

where the dimensionless parameter

$$\Omega^2 = \frac{3EI}{Ml^3} \frac{1}{\omega^2}$$

Special cases

1. A cantilever beam with rigid body at the free end; the rotational effect is neglected. In this case $r = 0$. The frequency parameter

$$\Omega^2 = 1 + \frac{3d}{l} + \frac{3d^2}{l^2}$$

2. A cantilever beam with lumped mass M at the free end; the rotational effect is neglected. In this case $r = d = 0$. The frequency parameter

$$\Omega = 1 \quad \text{and} \quad \omega^2 = \frac{3EI}{Ml^3}$$

2.3.2 Rayleigh method

The Rayleigh method, based on the Rayleigh quotient, expresses the equality of the maximum kinetic and strain energies for undamped free vibrations (Rayleigh, 1877). The method can be used to determine the upper bound of the fundamental frequency vibration of continuous systems.

The Rayleigh quotient and various types of Rayleigh method procedure are presented in Table 2.3 (Birger *et al.*, 1968). The vibrating object is a non-uniform beam with distributed masses $m(x)$, carrying a concentrated mass M that is placed at $x = x_s$, and a concentrated force P that acts at $x = x_j$ (version 4); the bending moment is $M(x)$ (version 2); the bending stiffness of the beam is $EI(x)$.

TABLE 2.3 Rayleigh's quotients

Version	Formula	Procedure
1	Rayleigh quotient	
	$\omega_n^2 = \frac{\int_0^l EI(x)[X_n''(x)]^2 dx}{\int_0^l m(x)X_n^2(x)dx + \sum_s M_s X_n^2(x_s)}$	<ol style="list-style-type: none"> Choose an assumed mode shape function $X(x)$; Calculate slope $X'(x)$
2	$\omega_n^2 = \frac{\int_0^l M^2(x)dx}{\int_0^l m(x)X_n^2(x)dx + \sum_s M_s X_n^2(x_s)}$	<ol style="list-style-type: none"> Choose an assumed mode shape function $X(x)$; Calculate a bending moment $M(x) = EI''(x)$
3	$\omega_n^2 = \frac{\int_0^l q(x)X(x)dx}{\int_0^l m(x)X_n^2(x)dx + \sum_s M_s X_n^2(x_s)}$	<ol style="list-style-type: none"> Choose an expression for the distributed load $q(x)$ Calculate $X(x)$ by integrating.
4	$\omega_n^2 = \frac{\int_0^l q(x)X(x)dx + \sum_j P_j X_n(x_j)}{\int_0^l m(x)X_n^2(x)dx + \sum_s M_s X_n^2(x_s)}$	<ol style="list-style-type: none"> Choose an expression for the distributed load $q(x)$ Calculate $X(x)$ by integrating.
5	$\omega_n^2 = g \frac{\int_0^l m(x)X(x)dx + \sum_s M_s X_n(x_s)}{\int_0^l m(x)X_n^2(x)dx + \sum_s M_s X_n^2(x_s)}$	<ol style="list-style-type: none"> Use an expression that corresponds to the actual distributed load $q = gm(x)$ Calculate $X(x)$ by integrating.

Notes

- The natural frequency vibration obtained by the Rayleigh quotient (method) is always larger than the true value of frequency: $\omega \geq \omega_{\text{real}}$.

2. The Rayleigh quotient gives exact results if:
- the chosen expressions for X coincide with the true eigenfunctions of vibration (versions 1 and 2);
 - the chosen expressions for $q(x)$ are proportional to the true inertial forces (versions 3 and 4).
- The assumed function expressions for beams with different boundary conditions are presented in Appendix C.
3. In order to take into account the effect of rotary inertia of the beam it is necessary to add to the denominator a term of the form

$$\int_{(l)} mI_z(x)[X'(x)]^2 dx$$

4. In order to take into account the effect of rotary inertia of the concentrated mass it is necessary to add to the denominator a term of the form

$$J[X'(x_s)]^2$$

where J is a mass moment of inertia and x_s is the ordinate of the attached mass.

5. The low bound of the fundamental frequency of vibration may be calculated by using Dunkerley's equation.

Example. Calculate the fundamental frequency of vibration of a cantilever beam $[X(l) = X'(l) = 0]$ using the Rayleigh method.

Solution. Version 1 (Rayleigh quotient). Choose an expression for the eigenfunction in a form that satisfies the boundary condition at $x = l$

$$X(x) = \left(1 - \frac{x}{l}\right)^2$$

Differentiating with respect to x

$$X''(x) = \frac{2}{l^2}$$

The Rayleigh quotient terms become

$$\begin{aligned} \int_0^l EI(X'')^2 dx &= \frac{4EI}{l^3} \\ \int_0^l mX^2 dx &= m \int_0^l \left(1 - \frac{x}{l}\right)^4 dx = \frac{ml}{5} \end{aligned}$$

Substituting these expressions into the Rayleigh quotient leads to the fundamental frequency vibration:

$$\omega^2 = \left(\frac{4EI}{l^3}\right) \Bigg/ \left(\frac{ml}{5}\right) = \frac{20EI}{ml^4}, \quad \omega = \frac{4.47}{l^2} \sqrt{\frac{EI}{m}}$$

The exact eigenvalue is equal to $\omega = \frac{3.5156}{l^2} \sqrt{\frac{EI}{m}}$.

Version 2. Choose an expression for the bending moment in the form

$$M(x) = \left(1 - \frac{x}{l}\right)^2$$

The differential equation is

$$EI X''(x) = \left(1 - \frac{x}{l}\right)^2$$

Integrating twice

$$\begin{aligned} EI X' &= -\frac{l}{3} \left(1 - \frac{x}{l}\right)^3 + C_1 \\ EI X &= \frac{l^2}{12} \left(1 - \frac{x}{l}\right)^4 + C_1 x + C_2 \end{aligned}$$

Boundary conditions: $X(l) = X'(l) = 0$, so the arbitrary constants are $C_1 = C_2 = 0$.

The eigenfunction is

$$X(x) = \frac{l^2}{12EI} \left(1 - \frac{x}{l}\right)^4$$

The Rayleigh quotient is

$$\omega^2 = \frac{\int_0^l \left(1 - \frac{x}{l}\right)^4 dx}{EI \int_0^l m \left[\frac{l^2}{12EI} \left(1 - \frac{x}{l}\right)^4 \right]^2 dx} = \frac{108EI}{5ml^4}$$

A frequency vibration equals

$$\omega = \frac{4.65}{l^2} \sqrt{\frac{EI}{m}}$$

Version 4. Choose an expression for eigenfunction $X(x)$ in a form that coincides with an elastic curve due to a concentrated force P applied at the free end

$$X(x) = \frac{Pl^3}{6EI} \left(\frac{x^3}{l^3} - \frac{3x}{l} + 2 \right)$$

The Rayleigh quotient is

$$\omega^2 = \frac{P \frac{Pl^3}{3EI}}{\int_0^l m \left(\frac{Pl^3}{6EI} \right)^2 \left(\frac{x^3}{l^3} - \frac{3x}{l} + 2 \right)^2 dx} = \frac{140EI}{11ml^4}$$

The fundamental frequency vibration equals

$$\omega = \frac{3.53}{l^2} \sqrt{\frac{EI}{m}}$$

Version 5. Choose an expression for eigenfunction $X(x)$ in a form that coincides with an elastic curve due to a uniformly distributed load $q = mg$ along the beam

$$X(x) = \frac{mg l^4}{8EI} \left(1 - \frac{4x}{3l} + \frac{x^4}{3l^4} \right)$$

Calculate:

$$\int_0^l mX(x)dx = \frac{m^2 gl^5}{20EI}$$

$$\int_0^l mX^2(x)dx = \frac{13m^3 g^2 l^9}{3240(EI)^2}$$

The Rayleigh quotient is

$$\omega^2 = g \frac{\int_0^l mX(x)dx}{\int_0^l mX^2(x)dx} = \frac{162EI}{13ml^4}$$

The fundamental frequency of vibration equals

$$\omega = \frac{3.52}{l^2} \sqrt{\frac{EI}{m}}$$

2.3.3 Rayleigh–Ritz Method

The Rayleigh–Ritz method (Rayleigh, 1877, Ritz, 1909) can be considered as an extension of the Rayleigh method. The method can be used not only to obtain a more accurate value of the fundamental natural frequency, but also to determine the higher frequencies and the associated mode shapes.

Procedure

1. Assume that the shape of deformation of the beam is in the form

$$y(x) = c_1 X_1(x) + c_2 X_2(x) + \dots = \sum_{i=1}^n c_i X_i(x) \quad (2.19)$$

which satisfies the geometric boundary conditions.

2. The frequency equation may be presented in two different canonical forms

Form 1

$$\begin{vmatrix} k_{11} - m_{11}\omega^2 & k_{12} - m_{12}\omega^2 & \dots \\ k_{21} - m_{21}\omega^2 & k_{22} - m_{22}\omega^2 & \dots \\ \dots & \dots & \dots \end{vmatrix} = 0 \quad (2.20)$$

The parameters of the frequency equation (2.20) are the mass and stiffness coefficients, which are expressed in terms of shape mode $X(x)$

$$m_{ij} = \int_0^l \rho A X_i' X_j dx \quad (2.21)$$

$$k_{ij} = \int_0^l E I X_i'' X_j'' dx$$

Form 2

$$\begin{vmatrix} m_{11} - V_{11}\omega^2 & m_{12} - V_{12}\omega^2 & \dots \\ m_{21} - V_{21}\omega^2 & m_{22} - V_{22}\omega^2 & \dots \\ \dots & \dots & \dots \end{vmatrix} = 0 \quad (2.22)$$

where m_{ij} is the mass stiffness coefficient (2.21). In the case of transverse vibration, the parameter of the frequency equation (2.22) is

$$V_{ij} = \int_0^l \frac{M_i M_k}{EI} dx \quad (2.23)$$

where bending moments M_i and M_k are caused by the loads mX_i and mX_k ; $m = \rho A$. If the assumed shape functions happen to be the exact eigenfunctions, the Rayleigh–Ritz method yields the exact eigenvalues.

The frequency equations in the different forms for first and second approximations are presented in Table 2.4.

TABLE 2.4 Rayleigh–Ritz frequency equations

Approximation	Form 1	Form 2
First	$k_{11} - m_{11}\omega^2 = 0$	$m_{11} - V_{11}\omega^2 = 0$
Second	$\begin{vmatrix} k_{11} - m_{11}\omega^2 & k_{12} - m_{12}\omega^2 \\ k_{21} - m_{21}\omega^2 & k_{22} - m_{22}\omega^2 \end{vmatrix} = 0$	$\begin{vmatrix} m_{11} - V_{11}\omega^2 & m_{12} - V_{12}\omega^2 \\ m_{21} - V_{21}\omega^2 & m_{22} - V_{22}\omega^2 \end{vmatrix} = 0$

Example. Calculate the first and second frequencies of a cantilever beam that has a uniform cross-sectional area A ; the beam is fixed at $x = 0$.

Solution

1. Assume that the shape of deformation of the beam is in the form

$$y(x) = \sum C_i X_i = C_1 \left(\frac{x}{l}\right)^2 + C_2 \left(\frac{x}{l}\right)^3$$

where functions X_i satisfy the geometry boundary conditions at the fixed end.

2. Using the expressions for the assumed shape functions, the mass coefficients are

$$m_{11} = \int_0^l m X_1^2(x) dx = \int_0^l m \left(\frac{x}{l}\right)^4 dx = \frac{ml}{5}$$

$$m_{12} = m_{21} = \int_0^l m X_1(x) X_2(x) dx = \int_0^l m \left(\frac{x}{l}\right)^5 dx = \frac{ml}{6}$$

$$m_{22} = \int_0^l m X_2^2(x) dx = \int_0^l m \left(\frac{x}{l}\right)^6 dx = \frac{ml}{7}$$

where $m = \rho A$ is the mass per unit length.

3. Using the expressions for assumed shape functions the stiffness coefficients are

$$\begin{aligned} k_{11} &= \int_0^l EI X_1'^2(x) dx = \int_0^l EI \left(\frac{2}{l^2}\right)^2 dx = \frac{4EI}{l^3} \\ k_{12} = k_{21} &= \int_0^l EI X_1''(x) X_2''(x) dx = \int_0^l EI \frac{2}{l^2} \frac{6x}{l^3} dx = \frac{6EI}{l^3} \\ k_{22} &= \int_0^l EI X_2'^2(x) dx = \int_0^l EI \left(\frac{6x}{l^3}\right)^2 dx = \frac{12EI}{l^3} \end{aligned}$$

4. The frequency equation, using the first form, is

$$D = \begin{vmatrix} 4 - \frac{ml^4}{5EI}\omega^2 & 6 - \frac{ml^4}{6EI}\omega^2 \\ 6 - \frac{ml^4}{6EI}\omega^2 & 12 - \frac{ml^4}{7EI}\omega^2 \end{vmatrix} = 0$$

First approximation. The frequency equation yields the linear equation with respect to eigenvalue λ

$$4 - \frac{\lambda}{5} = 0, \quad \lambda = \omega^2 \frac{ml^4}{EI}$$

The fundamental frequency of vibration is

$$\omega_1 = \frac{4.4721}{l^2} \sqrt{\frac{EI}{m}}$$

Second approximation. The frequency equation yields the quadratic equation with respect to eigenvalues λ :

$$\lambda^2 - 1224\lambda + 15121 = 0$$

The eigenvalues of the problem are

$$\lambda_1 = 12.4802, \quad \lambda_2 = 1211.519$$

The fundamental and second frequencies of vibration are

$$\omega_1 = \frac{3.5327}{l^2} \sqrt{\frac{EI}{m}}, \quad \omega_2 = \frac{34.8068}{l^2} \sqrt{\frac{EI}{m}}$$

The exact fundamental frequency of vibration is equal to

$$\omega = \frac{3.5156}{l^2} \sqrt{\frac{EI}{m}}$$

Comparing the results obtained in both approximations shows that the eigenvalues differed widely. The second approximation yields a large dividend in accuracy for the fundamental frequency of vibration. A significant improvement in the fundamental, second and higher frequencies of vibration can be achieved by increasing the number of terms in the expression for the mode shape of vibration.

2.3.4 Bubnov–Galerkin Method

The Bubnov–Galerkin method can be used to determine the fundamental frequency and several lower natural frequencies, both linear and nonlinear, of the continuous systems (Galerkin, 1915).

Procedure

1. Choose a trial shape function, $X(x)$, that satisfies the kinematic and dynamic boundary conditions and presents the deformable shape in the form

$$y(x) = c_1 X_1(x) + c_2 X_2(x) \dots = \sum_{i=1}^n c_i X_i(x) \quad (2.24)$$

where c_i are unknown coefficients.

2. Formulas for mass and stiffness coefficients are presented in Table 2.5.
3. Frequency equation (Common formula)

$$\begin{vmatrix} k_{11} - m_{11}\omega^2 & k_{12} - m_{12}\omega^2 & \dots \\ k_{21} - m_{21}\omega^2 & k_{22} - m_{22}\omega^2 & \dots \\ \dots & \dots & \dots \end{vmatrix} = 0 \quad (2.25)$$

First approximation for the frequency of vibration

$$k_{11} - m_{11}\omega^2 = 0 \quad (2.26)$$

Second approximation for the frequency of vibration

$$\begin{vmatrix} k_{11} - m_{11}\omega^2 & k_{12} - m_{12}\omega^2 \\ k_{21} - m_{21}\omega^2 & k_{22} - m_{22}\omega^2 \end{vmatrix} = 0 \quad (2.27)$$

As may be seen from the Equation (2.21) and Table 2.5, the mass coefficients for the Rayleigh–Ritz and Bubnov–Galerkin methods coincide, while the stiffness coefficients are different.

TABLE 2.5 Mass and stiffness coefficients for different types of vibration

Vibration	Mass coefficient	Stiffness coefficient
Transversal	$m_{ij} = \int_0^l \rho A X_i X_j \, dx$	$k_{ij} = \int_0^l (E I X_i'')'' X_j \, dx$
Longitudinal	$m_{ij} = \int_0^l \rho A X_i X_j \, dx$	$k_{ij} = - \int_0^l (E A X_i')' X_j \, dx$
Torsional	$m_{ij} = \int_0^l \rho A X_i X_j \, dx$	$k_{ij} = - \int_0^l (G I_p X_i')' X_j \, dx$

Example. Calculate the fundamental frequency of vibration of the beam shown in Fig. 2.18 (beam thickness is equal to unity).

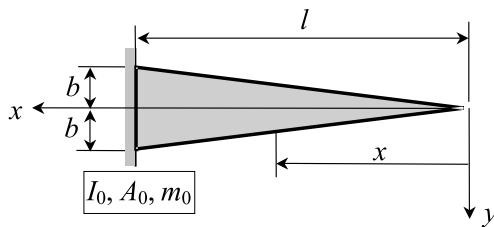

FIGURE 2.18. Cantilevered non-uniform beam.

Solution. The second moment of inertia, cross-sectional area and distributed mass at any position x are

$$I_x = I_0 \left(\frac{x}{l}\right)^3 = \frac{2}{3} b^3 \left(\frac{x}{l}\right)^3; \quad A_x = A_0 \frac{x}{l} = 2b \frac{x}{l}; \quad m_x = m_0 \frac{x}{l} = 2b\rho \frac{x}{l}$$

1. The boundary conditions of the beam are

$$y(l) = 0, \quad y'(l) = 0, \quad EIy''(0) = 0; \quad EIy'''(0) = 0$$

so the function $y(x)$ for the transversal displacement may be chosen as

$$y(x) = C_1 X_1(x) + C_2 X_2(x)$$

where the assumed functions are

$$X_1(x) = \left(\frac{x}{l} - 1\right)^2; \quad X_2(x) = \left(\frac{x}{l} - 1\right)^2 \frac{x}{l}$$

First approximation. In this case we have to take into account only function X_1

$$X_1'' = \frac{2}{l^2}; \quad EI X_1'' = EI_0 \frac{x^3}{l^5} \frac{2}{l^2}; \quad (EI X_1'')'' = EI_0 \frac{12x}{l^5}$$

The stiffness and mass coefficients are

$$k_{11} = \int_0^l (EI X_1'')'' X_1 \, dx = \int_0^l EI_0 \frac{12x}{l^5} \left(\frac{x^2}{l^2} - \frac{2x}{l} + 1\right) dx = \frac{EI_0}{l^3}$$

$$m_{11} = \int_0^l \rho A X_1^2 \, dx = \int_0^l m_0 \frac{x}{l} \left(\frac{x^2}{l^2} - \frac{2x}{l} + 1\right)^2 dx = m_0 \frac{l}{30}$$

The frequency equation is $k_{11} - m_{11}\omega^2 = 0$.

The fundamental frequency of vibration is

$$\omega^2 = \frac{30EI_0}{m_0 l^4} \quad \text{or} \quad \omega^2 = \frac{30EB^2}{3\rho l^4} \quad \text{and} \quad \omega = 5.48 \frac{b}{l^2} \sqrt{\frac{E}{3\rho}}$$

Second approximation. In this case we have to take into account both functions X_1 and X_2

$$X_2'' = \frac{6x}{l^3} - \frac{4}{l^2}; \quad EI X_2'' = EI_0 \left(\frac{6x^4}{l^6} - \frac{4x^3}{l^5}\right); \quad (EI X_2'')'' = EI_0 \left(\frac{72x^2}{l^6} - \frac{24x}{l^5}\right)$$

The stiffness and mass coefficients that correspond to the second assumed function are

$$\begin{aligned} k_{22} &= \int_0^l (EI X_2'')'' X_2 \, dx = \int_0^l EI_0 \left(\frac{72x^2}{l^6} - \frac{24x}{l^5} \right) \left(\frac{x^3}{l^3} - \frac{2x^2}{l^2} + \frac{x}{l} \right) dx = \frac{2EI_0}{5l^3} \\ m_{22} &= \int_0^l \rho A X_2^2 \, dx = \int_0^l m_0 \frac{x}{l} \left(\frac{x^3}{l^3} - \frac{2x^2}{l^2} + \frac{x}{l} \right)^2 dx = m_0 \frac{l}{280} \\ k_{12} &= \int_0^l (EI X_1'')'' X_2 \, dx = \int_0^l EI_0 \frac{12x}{l^5} \left(\frac{x^3}{l^3} - \frac{2x^2}{l^2} + \frac{x}{l} \right) dx = \frac{2EI_0}{5l^3} \\ m_{12} &= \int_0^l \rho A X_1 X_2 \, dx = \int_0^l m_0 \frac{x}{l} \left(\frac{x^2}{l^2} - \frac{2x}{l} + 1 \right) \left(\frac{x^3}{l^3} - \frac{2x^2}{l^2} + \frac{x}{l} \right) dx = m_0 \frac{l}{105} \end{aligned}$$

Frequency equation:

$$\left(\frac{EI_0}{l^3} - \frac{m_0 l}{30} \omega^2 \right) \left(\frac{2EI_0}{5l^3} - \frac{m_0 l}{280} \omega^2 \right) - \left(\frac{2EI_0}{5l^3} - \frac{m_0 l}{105} \omega^2 \right)^2 = 0$$

Fundamental frequency (Pratusevich, 1948)

$$\omega = \frac{5.319}{l^2} \sqrt{\frac{EI_0}{m_0}} \quad \text{or} \quad \omega = 5.319 \frac{b}{l^2} \sqrt{\frac{E}{3\rho}}$$

The exact fundamental frequency, obtained by using Bessel's function is

$$\omega = 5.315 \frac{b}{l^2} \sqrt{\frac{E}{3\rho}}$$

This is the result obtained by Kirchhoff (1879).

A comparison of the Bubnov–Galerkin method and the related ones is given in Bolotin (1978).

The Bubnov–Galerkin method may be applied for deformable systems that are described by partial nonlinear differential equations.

Example. Show the Bubnov–Galerkin procedure for solving the differential equation of a nonlinear transverse vibration of a simply supported beam.

The type of nonlinearity is a physical one, the characteristics of hardening are hard characteristics. This means that the 'Stress–strain' relationship is $\sigma = E\varepsilon + \beta\varepsilon^3$, $\beta > 0$, where β is a nonlinearity parameter (see Chapter 14).

Solution. The differential equation of the free transverse vibration is

$$L(y, t) \cong EI_2 \frac{\partial^4 y}{\partial x^4} + 6\beta I_4 \frac{\partial^2 y}{\partial x^2} \left(\frac{\partial^3 y}{\partial x^3} \right)^2 + 3\beta I_4 \left(\frac{\partial^2 y}{\partial x^2} \right)^2 \frac{\partial^4 y}{\partial x^4} + m \frac{\partial^2 y}{\partial t^2} = 0$$

where $L(y, t)$ is the nonlinear operator; and I_n is the moment of inertia of order n of the cross-section area

$$I_n = \int_{(A)} y^n \, dA$$

For a rectangular section, $b \times h$: $I_2 = bh^3/12$, $I_4 = bh^5/80$; for a circle section of diameter d : $I_2 = \pi d^4/64$, $I_4 = \pi d^6/512$.

The bending moment of the beam equals

$$M = -y''[EI_2 + \beta I_4(y'')^2]$$

First approximation. A transverse displacement of a simply supported beam may be presented in the form

$$y(x, t) = f_1(t) \sin \frac{\pi x}{l}$$

Using the Bubnov–Galerkin procedure

$$\begin{aligned} \int_0^l L(x, t) \sin \frac{\pi x}{l} dx &= 0 \\ \int_0^l \left[EI_2 \frac{\partial^4 y}{\partial x^4} + 6\beta I_4 \frac{\partial^2 y}{\partial x^2} \left(\frac{\partial^3 y}{\partial x^3} \right)^2 + 3\beta I_4 \left(\frac{\partial^2 y}{\partial x^2} \right)^2 \frac{\partial^4 y}{\partial x^4} + m \frac{\partial^2 y}{\partial t^2} \right] \sin \frac{\pi x}{l} dx &= 0 \end{aligned} \quad (2.28)$$

This algorithm yields one nonlinear ordinary differential equation with respect to an unknown function $f_1(t)$.

Second approximation. A transverse displacement may be presented in the form

$$y(x, t) = f_1(t) \sin \frac{\pi x}{l} + f_2(t) \sin \frac{2\pi x}{l}$$

Using the Bubnov–Galerkin method

$$\begin{aligned} \int_0^l L(x, t) \sin \frac{\pi x}{l} dx &= 0 \\ \int_0^l L(x, t) \sin \frac{2\pi x}{l} dx &= 0 \end{aligned} \quad (2.29)$$

This algorithm yields two nonlinear ordinary differential equations with respect to unknown functions $f_1(t)$ and $f_2(t)$.

2.3.5 Grammel's Formula

Grammel's formula can be used to determine the fundamental natural frequency of continuous systems, and it gives a more exact result than the Rayleigh method for the same function $X(x)$. Grammel's quotients always lead to an approximate fundamental frequency that is higher than the exact one. Grammel's quotients for different types of vibration are presented in Table 2.6.

In Table 2.6, $M(x)$ denotes the bending moment along the beam, m is the distributed mass, M_i is the concentrated masses and X_i is the ordinate of the mode shape at the point of mass M_i .

TABLE 2.6 Grammel's quotients

Type of vibration	Square frequency
Longitudinal	$\omega^2 = \frac{\int_0^l mX^2(x)dx + \sum M_i X_i^2}{\int_0^l \frac{N^2(x)dx}{EA}}$
Torsional	$\omega^2 = \frac{\int_0^l IX^2(x)dx + \sum I_i X_i^2}{\int_0^l \frac{M_t^2(x)dx}{GI_p}}$
Transversal	$\omega^2 = \frac{\int_0^l mx^2(x)dx + \sum M_i X_i^2}{\int_0^l \frac{M^2(x)dx}{EJ}}$

Example. Calculate the frequency of free vibration of a cantilever beam.

Solution

- Choose the expression for $X(x)$ in the form

$$X(x) = \left(1 - \frac{4x}{3l} + \frac{x^4}{3l^4} \right)$$

- Take the distributed load in the form

$$q(x) = mX(x) = m\left(1 - \frac{4x}{3l} + \frac{x^4}{3l^4} \right)$$

- Define the bending moment $M(x)$ by integrating the differential equation $M''(x) = q(x)$ twice

$$M(x) = m\left(\frac{x^2}{2} - \frac{2x^3}{9l} + \frac{x^6}{90l^4} \right)$$

- It follows that

$$\int_0^l mX^2 dx = 0.2568ml$$

$$\int_0^l \frac{M^2(x)dx}{EI} = 0.02077 \frac{m^2 l^5}{EI}$$

- Substituting these expressions into the Grammel quotient, one obtains

$$\omega = \frac{3.51}{l^2} \sqrt{\frac{EI}{m}}$$

2.3.6 Hohenemser–Prager Formula

The Hohenemser–Prager formula can be used for a rough evaluation of the fundamental frequency of vibration of a deformable system (Hohenemser and Prager, 1932).

The Hohenemser–Prager quotients for different types of vibration are presented in Table 2.7.

TABLE 2.7 Hohenemser–Prager's quotients

Type of vibration	Square of frequency vibration
Longitudinal	$\int_0^l \frac{(N')^2}{m} dx / \int_0^l \frac{N^2(x)dx}{EA}$
Torsional	$\int_0^l \frac{(M'_t)^2}{I} dx / \int_0^l \frac{M_t^2(x)dx}{GI_p}$
Transversal	$\int_0^l \frac{(M'')^2}{m} dx / \int_0^l \frac{M^2(x)dx}{EI}$

Example. Calculate the first frequency of vibration of a cantilever beam that has a uniform cross-sectional area.

Solution

- Assume that elastic curve under vibration coincides with the elastic curve caused by uniformly distributed inertial load q . In this case the bending moment $M(x) = qx^2/2$. It follows that

$$\begin{aligned}\int_0^l (M'')^2 dx &= \frac{q^2 l}{m} \\ \int_0^l \frac{M^2}{EI} dx &= \frac{q^2 l^5}{20EI}\end{aligned}$$

- Substituting these expressions into the Hohenemser–Prager quotient, one obtains

$$\omega^2 = \frac{20EI}{ml^4} \rightarrow \omega = \frac{4.47}{l^2} \sqrt{\frac{EI}{m}}$$

2.3.7 Dunkerley Formula

The Dunkerley formula gives the lower bound of the fundamental frequency of vibration (Dunkerley, 1894). The Dunkerley formula may be written in two forms. Form 1 is presented in Table 2.8.

The influence coefficient $\delta(x, x)$ is linear (angular) deflection of the point with abscissa x due to the unit force (moment) being applied at the same point. For pinned–pinned, clamped–clamped, clamped–free and clamped–pinned beams, the linear influence coefficient $\delta(x, x)$ is presented in Table 2.1.

TABLE 2.8 Dunkerley first form

Type of vibration	Square frequency vibration
Transversal and longitudinal	$\omega^2 = 1 \left/ \left[\int_0^l m(x) \delta(x, x) dx + \sum M_i \delta(x_i, x_i) \right] \right.$
Torsional	$\omega^2 = 1 \left/ \left[\int_0^l I(x) \delta(x, x) dx + \sum I_i \delta(x_i, x_i) \right] \right.$

Example. Calculate the fundamental frequency vibration of the cantilever uniform cross-section beam carrying concentrated mass M at the free end (Fig. 2.19).

Solution

1. The influence function is

$$\delta(x, x) = \frac{x^3}{3EI}$$

It follows that

$$\int_0^l \delta(x, x) dx = \frac{l^4}{12EI}$$

3. Substituting these expressions into the Dunkerley quotient, one obtains

$$\omega^2 = \frac{1}{\frac{ml^4}{12EI} + \frac{Ml^3}{3EI}} = \frac{12EI}{ml^4 \left(1 + 4 \frac{M}{ml} \right)}$$

Special cases

1. If $M = 0$, then $\omega = \frac{1.86^2}{l^2} \sqrt{\frac{EI}{m}}$.

For comparison, the exact value is $\omega = \frac{1.875^2}{l^2} \sqrt{\frac{EI}{m}}$ (see Table 5.3).

2. If $M = ml$, then $\omega = \frac{1.244^2}{l^2} \sqrt{\frac{EI}{m}}$.

Exact value $\omega = \frac{1.248^2}{l^2} \sqrt{\frac{EI}{m}}$ (from Table 7.7). See also Table 7.6.

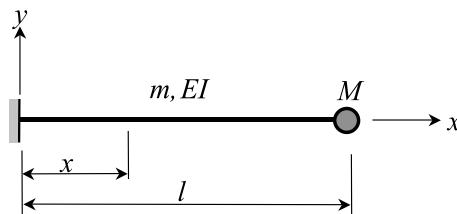

FIGURE 2.19. Cantilever beam with a lumped mass at the free end.

Dunkerley second formula. The Dunkerley formula gives the lower bound of the fundamental and second frequencies of vibration of a composite system in terms of the frequencies of vibration of the system's partial systems.

The partial systems are those that are obtained from a given system if all coordinates except one are deleted. In the case of a deformable system with lumped masses and neglecting a distributed mass, the partial systems have one degree of freedom. If a distributed mass is also taken into account, then one of the partial systems is continuous.

The partial systems may be obtained from a given system by using a mathematical model or design diagram. In the first case, the connections between generalized coordinates must be deleted. In the second case, all masses except one must be equal to zero.

The relationship between the fundamental frequency of the actual system and partial frequencies is

$$\frac{1}{\omega_{1r}^2} < \frac{1}{\omega_1^2} + \frac{1}{\omega_2^2} + \cdots + \frac{1}{\omega_n^2} \quad (2.30)$$

Since a partial frequency

$$\omega_n = \sqrt{\frac{1}{\delta_{nn} m_n}} \quad (2.31)$$

then the square of the frequency of vibration of the given system is

$$\omega_{1r}^2 \approx \frac{1}{\delta_{11} m_1 + \delta_{22} m_2 + \cdots + \delta_{kk} m_k} \quad (2.32)$$

where ω_{1r} and ω_{2r} are fundamental and second frequencies of vibration of the given system;

$\omega_1, \dots, \omega_j$ are partial frequencies of vibration;

$\delta_{n,n}$ are unit displacements of the structure at the point of attachment of mass m_n .

Each term on the right-hand side of Equation (2.30) presents the contribution of each mass in the absence of all other masses. The fundamental frequency given by Equation (2.30) will always be smaller than the exact value.

The relationship between the second frequency of the actual system and parameters of system is

$$\omega_{2r}^2 \approx \frac{\delta_{11} m_1 + \delta_{22} m_2 + \cdots + \delta_{kk} m_k}{\left| \begin{array}{cc} \delta_{11} m_1 & \delta_{12} m_2 \\ \delta_{21} m_1 & \delta_{22} m_2 \end{array} \right| + \cdots + \left| \begin{array}{cc} \delta_{k-1,k-1} m_{k-1} & \delta_{k-1,k} m_k \\ \delta_{k,k-1} m_{k-1} & \delta_{kk} m_k \end{array} \right|} \quad (2.33)$$

Example. Calculate the fundamental frequency of vibration of the cantilever uniformly massless beam carrying two lumped masses M_1 and M_2 , as shown in Fig. 2.20.

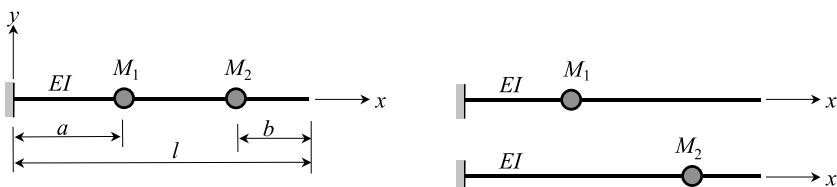

FIGURE 2.20. Deformable system with two degrees of freedom and two partial systems.

Solution. The first and second partial frequencies according to Equation (2.31) are

$$\omega_1^2 = \frac{1}{M_1 \delta_{11}}, \quad \delta_{11} = \frac{a^3}{3EI}$$

$$\omega_2^2 = \frac{1}{M_2 \delta_{22}}, \quad \delta_{22} = \frac{(l-b)^3}{3EI}$$

The fundamental frequency of vibration of the real system is

$$\omega_{1r}^2 \approx \frac{1}{\delta_{11}m_1 + \delta_{22}m_2}$$

The second frequency of vibration of the real system is

$$\omega_{2r}^2 \approx \frac{\delta_{11}m_1 + \delta_{22}m_2}{\begin{vmatrix} \delta_{11}m_1 & \delta_{12}m_2 \\ \delta_{12}m_1 & \delta_{22}m_2 \end{vmatrix}} = \frac{\delta_{11}m_1 + \delta_{22}m_2}{\delta_{11}m_1\delta_{22}m_2 - m_1m_2\delta_{12}^2}$$

$$\delta_{12} = \frac{a^2}{2EI} \left(l - b - \frac{a}{3} \right)$$

Here, unit displacement δ_{12} is taken from Table 2.1. This table may also be used for calculation of the frequencies of vibration of a beam with different boundary conditions.

Example. Calculate the fundamental frequency of vibration of the cantilever uniform beam carrying lumped mass M at the free end (Fig. 2.21).

Solution. The partial systems are a continuous beam with distributed masses m and a one-degree-of-freedom system, which is a lumped mass on a massless beam.

1. The frequency of vibration for a cantilever beam by itself is

$$\omega_1^2 = \frac{1.875^4 EI}{l^4} = \frac{3.515^2 EI}{l^4}$$

2. The frequency of vibration for the concentrated mass by itself, attached to a weightless cantilever beam, is

$$\omega_2^2 = \frac{1}{\delta_{st}M} = \frac{3EI}{Ml^3}$$

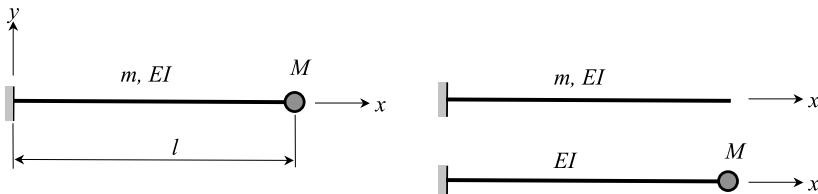

FIGURE 2.21. Continuous deformable system with lumped mass and two partial systems.

3. The square of the frequency of vibration for the given system, according to Equation (2.30), is

$$\omega^2 = \frac{\omega_1^2 \omega_2^2}{\omega_1^2 + \omega_2^2} = \frac{\omega_1^2}{1 + \frac{\omega_1^2}{\omega_2^2}} = \frac{3.515^2 EI}{l^4 m} \frac{1}{1 + 4.1184 \frac{M}{ml}}$$

2.3.8 Approximate estimations (spectral function method)

The spectral function method is proficient at calculating the fundamental and second frequencies of vibration. In particular, this method is effective for a system with a large number of lumped masses.

Bernstein's estimations (Bernstein, 1941). Bernstein's first formula gives upper and lower estimates of the fundamental frequency

$$\frac{1}{\sqrt{B_2}} < \omega_1^2 < \frac{2}{B_1 + \sqrt{2B_2 - B_1^2}} \quad (2.34)$$

Bernstein's second formula gives a lower estimate of the second frequency of vibration

$$\omega_2^2 > \frac{2}{B_1 - \sqrt{2B_2 - B_1^2}} \quad (2.35)$$

where B_1 and B_2 are parameters

$$\begin{aligned} B_1 &= \int_0^l m(x) \delta(x, x) dx + \sum_i M_i \delta(x_i, x_i) \\ B_2 &= \int_0^l \int_0^l m(x) m(s) \delta(x, s) dx ds + \sum_i \sum_k M_i M_k \delta(x_i, x_k) \end{aligned} \quad (2.36)$$

where δ is the influence coefficient;

M is the lumped mass;

m is the distributed mass;

l is the length of a beam.

The expressions for influence coefficient, δ , for beams with a classical boundary condition are presented in Table 2.1 and for a beam with elastic supports in Table 2.2.

Example. Find the lowest eigenvalue for a cantilever beam (Fig. 2.22)

Solution

1. Unit displacements for fixed-free beam are (Table 2.1, case 3)

$$\delta_{xx} = \frac{x^3}{3EI}, \quad \delta_{xs} = \frac{1}{6EI}(3x^2s - x^3)$$

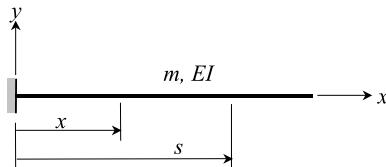

FIGURE 2.22. Cantilever uniform beam.

2. It follows that Bernstein's parameters are

$$B_1 = \int_0^l m(x)\delta(x, x)dx = \int_0^l m \frac{x^3}{3EI} dx = \frac{ml^4}{12EI}$$

$$B_2 = \iint_{0,0}^{l,l} m(x)m(s)\delta(x, s)dx ds = \iint_{0,0}^{l,l} m^2 \left[\frac{1}{6EI} (3x^2s - x^3) \right]^2 dx ds = \frac{11m^2l^8}{1680(EI)^2}$$

3. Bernstein's estimations give the upper and lower bounds to the fundamental frequency

$$12.360 \frac{EI}{ml^4} < \omega_1^2 < 12.364 \frac{EI}{ml^4} \quad \text{or} \quad \frac{3.5153}{l^2} \sqrt{\frac{EI}{m}} < \omega_1 < \frac{3.516}{l^2} \sqrt{\frac{EI}{m}}$$

The fundamental frequency of vibration is situated within narrow limits.

Bernstein–Smirnov's estimation. The Bernstein–Smirnov's estimation gives upper and lower estimates of the fundamental frequency of vibration

$$\frac{1}{\sqrt[4]{B_2}} < \omega_1 < \sqrt{\frac{B_1}{B_2}} \quad (2.37)$$

In the case of lumped masses only, the distributed mass of the beam is neglected

$$B_1 = \sum \delta_{ii} m_i$$

$$B_2 = \sum \delta_{ii} m_i^2 + 2 \sum \delta_{ik} m_i m_k \quad (2.38)$$

where δ_{ii} , δ_{ik} are principal and side displacements, respectively, in the system, due to unit forces applied to concentrated masses m_i and m_k (Smirnov, 1947).

Example. Find the fundamental frequency vibration for a beam shown in Fig. 2.23.

Solution

1. Bending moment diagrams due to unit inertial forces that are applied to all masses are shown in Fig. 2.23

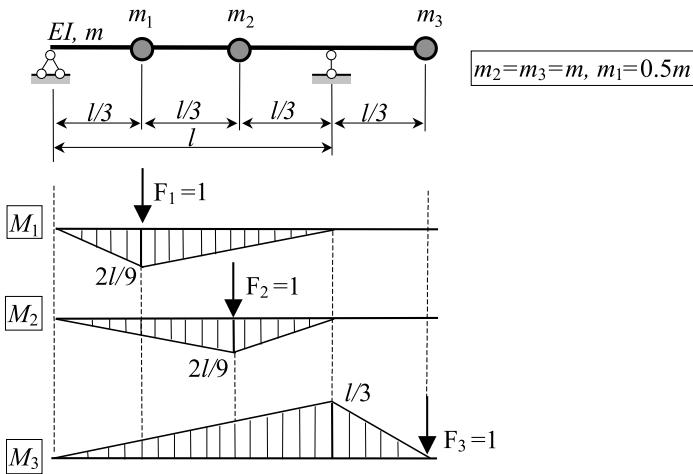

FIGURE 2.23. Pinned-pinned beam with an overhang carrying concentrated masses; M_1, M_2, M_3 are bending moment diagrams due to unit concentrated forces which are applied to masses m_1, m_2 , and m_3 , respectively.

2. Displacements calculated using the unit bending moment diagrams by Vereshchagin's rule are

$$\delta_{ik} = \sum \int \frac{M_i(x) \cdot M_k(x)}{EI} dx, \quad \delta_{ik} = \delta_{ki}$$

$$\delta_{11} = \delta_{22} = \frac{8l^3}{486EI}; \quad \delta_{12} = \delta_{21} = \frac{7l^3}{486EI}$$

$$\delta_{13} = \delta_{31} = -\frac{8l^3}{486EI}; \quad \delta_{23} = \delta_{32} = -\frac{10l^3}{486EI}; \quad \delta_{33} = \frac{24l^3}{486EI}$$

3. Bernstein-Smirnov's parameters

$$B_1 = \delta_{11}m_1 + \delta_{22}m_2 + \delta_{33}m_3 = \frac{48l^3m}{486EI}$$

$$B_2 = \delta_{11}^2m_1^2 + \delta_{22}^2m_2^2 + \delta_{33}^2m_3^2 + 2(\delta_{12}^2m_1m_2 + \delta_{23}^2m_2m_3 + \delta_{13}^2m_1m_3)$$

$$= 1620 \left(\frac{ml^3}{486EI} \right)^2$$

4. The fundamental frequency lies in the following range:

- (a) using the Bernstein-Smirnov estimation

$$\omega_1 > \frac{1}{\sqrt[4]{B_2}} = 3.48 \sqrt{\frac{EI}{ml^3}} \quad \text{and} \quad \omega_1 < \sqrt{\frac{B_1}{B_2}} = 3.70 \sqrt{\frac{EI}{ml^3}}$$

(b) using Bernstein's first formula

$$\omega_1 < \frac{1}{\sqrt{\frac{B_1}{2} \left(1 + \sqrt{\frac{2B_2}{B_1^2}} - 1 \right)}} = 3.52 \sqrt{\frac{EI}{ml^3}}$$

The fundamental frequency of vibration is situated within narrow limits.

Example. Estimate the fundamental frequency of vibration for a symmetric three-hinged frame with lumped masses, shown in Fig. 2.24(a); $M_2 = M_4 = M$, $M_1 = M_3 = 2M$, $l = h$, $EI = \text{constant}$; AS = axis of symmetry.

Solution. The given system has five degrees of freedom. The vibration of the symmetrical frame may be separated as symmetrical and antisymmetrical vibrations; the corresponding half-frames are presented in Figs. 2.24(b) and Fig. 2.24(c).

Symmetrical vibration

1. The half-frame has two degrees of freedom. The frequency equation in inverted form is

$$D = \begin{vmatrix} M_1 \delta_{11} \omega^2 - 1 & M_2 \delta_{12} \omega^2 \\ M_1 \delta_{21} \omega^2 & M_2 \delta_{22} \omega^2 - 1 \end{vmatrix} = 0$$

where δ_{ik} are unit displacements.

Fundamental frequency of vibration

$$\omega^2 = \frac{1}{2(\delta_{11}\delta_{22} - \delta_{12}^2)M_1M_2} \times \left[M_1\delta_{11} + M_2\delta_{22} - \sqrt{(M_1\delta_{11} + M_2\delta_{22})^2 - 4M_1M_2(\delta_{11}\delta_{22} - \delta_{12}^2)^2} \right]$$

2. The bending moment diagram due to unit inertial forces is presented in Fig. 2.25.

3. Unit displacements obtained by multiplication of bending moment diagrams are

$$\delta_{11} = \frac{5l^3}{192EI}, \quad \delta_{22} = \frac{4l^3}{192EI}, \quad \delta_{12} = \delta_{21} = \frac{3l^3}{192EI}$$

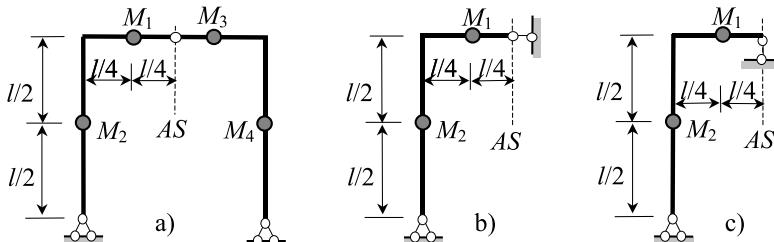

FIGURE 2.24. (a) Symmetrical three-hinged frame; (b) and (c) corresponding half-frame for symmetrical and antisymmetrical vibration.

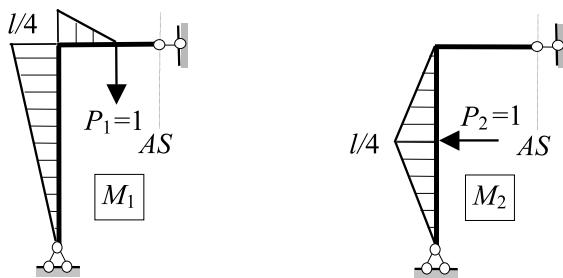

FIGURE 2.25. Symmetrical vibration analysis. Bending moment diagrams due to unit forces $P_1 = 1$ and $P_2 = 1$.

4. Frequency vibration

$$\begin{aligned}\omega^2 &= \frac{1}{2(5 \times 4 - 3^2) \times 2 \times 1} \\ &\times \left[2 \times 5 + 1 \times 4 - \sqrt{(2 \times 5 + 1 \times 4)^2 - 4 \times 2 \times 1(5 \times 4 - 3^2)^2} \right] \frac{192EI}{Ml^3} \\ \omega &= 3.97 \sqrt{\frac{EI}{Ml^3}}\end{aligned}$$

Antisymmetrical vibration

1. The half-frame has three degrees of freedom (see Fig. 2.26).
2. Unit displacements obtained by multiplication of bending moment diagrams are

$$\begin{aligned}\delta_{11} &= \frac{l^3}{384EI}, \quad \delta_{22} = \frac{5l^3}{24EI} = \frac{80l^3}{384EI}, \quad \delta_{33} = \frac{l^3}{2EI} = \frac{192l^3}{384EI} \\ \delta_{12} &= \delta_{21} = \frac{l^3}{128EI} = \frac{3l^3}{384EI} \\ \delta_{13} &= \delta_{31} = \frac{l^3}{64EI} = \frac{6l^3}{384EI} \\ \delta_{23} &= \delta_{32} = \frac{5l^3}{16EI} = \frac{120l^3}{384EI}\end{aligned}$$

3. Bernstein parameters

$$\begin{aligned}B_1 &= \sum \delta_{ii} m_i = (2 \times 1 + 1 \times 80 + 2 \times 192) \frac{Ml^3}{384EI} = \frac{466Ml^3}{384EI} \\ B_2 &= \sum \delta_{ii}^2 m_i^2 + 2 \sum \delta_{ik}^2 m_i m_k \\ B_2 &= [(2^2 \times 1^2 + 1^2 \times 80^2 + 2^2 \times 192^2) \\ &+ 2(2 \times 1 \times 3^2 + 2 \times 2 \times 6^2 + 1 \times 2 \times 120^2)] \times \frac{M^2 l^6}{(384EI)^2} = \frac{211784M^2 l^6}{(384EI)^2}\end{aligned}$$

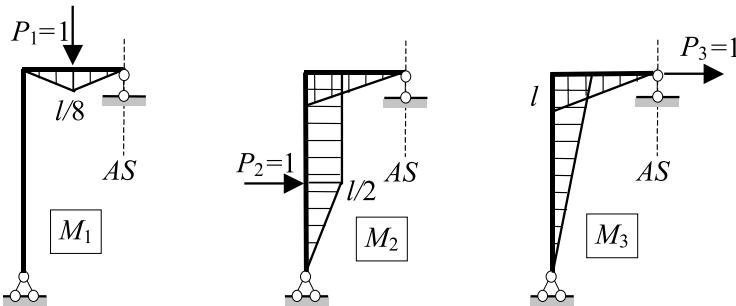

FIGURE 2.26. Antisymmetrical vibration analysis. Bending moment diagrams due to unit forces $P_1 = 1$, $P_2 = 1$ and $P_3 = 1$.

4. Bernstein first formula

$$\frac{1}{\sqrt{B_2}} < \omega_1^2 < \frac{2}{B_1 + \sqrt{2B_2 - B_1^2}}$$

$$\frac{1}{\frac{Ml^3\sqrt{211784}}{384EI}} < \omega_1^2 < \frac{2}{\frac{466Ml^3}{384EI} \left(1 + \sqrt{2 \frac{211784}{466^2} - 1}\right)}$$

So the fundamental frequency vibration satisfies the following condition

$$0.9134\sqrt{\frac{EI}{Ml^3}} < \omega < 0.9136\sqrt{\frac{EI}{Ml^3}}$$

ANALYSIS METHODS

CHAPTER 3

FUNDAMENTAL EQUATIONS OF CLASSICAL BEAM THEORY

This chapter covers the fundamental aspects of transverse vibrations of beams. Among the aspects covered are mathematical models for different beam theories, boundary conditions, compatibility conditions, energetic expressions, and properties of the eigenfunctions. The assumptions for different beam theories were presented in Chapter 1.

NOTATION

A	Cross-section area
D	Rayleigh dissipation function
DS	Deformable system
E, G	Young's modulus and modulus of rigidity
EI	Bending stiffness
F, V	Shear force
g	Gravitational acceleration
$G(x, \xi, t, \tau)$	Green function
H	Heaviside function
I_z	Moment of inertia of a cross-section
j	Pure imaginary number, $j^2 = -1$
k	Shear factor
$k_{\text{tr}}, k_{\text{rot}}$	Stiffness coefficients of elastic supports
k_b	Flexural wave number
l	Length of the beam
MCD	Mechanical chain diagram (Mechanical network)
m_j, k_j	Mass and stiffness coefficients
M, J	Concentrated mass and moment inertia of the mass
N, M	Axial force, bending moment
$P(t), P_0$	Force and amplitude of a force
r	Dimensionless radius of gyration, $r^2 A l^2 = I$
$r_{\text{tr}}, r_{\text{rot}}$	Transversal and rotational stiffness of foundation

R_x	Reaction of the foundation
s	Dimensionless parameter, $s^2 kAGl^2 = EI$
t	Time
U, T	Potential and kinetic energy
U, V	Real and imaginary parts of an impedance, $Z = U + j\omega V$
VPD	Vibroprotective device
$W(x, \xi, p)$	Transfer function
x	Spatial coordinate
$X(x)$	Mode shape
x, y, z	Cartesian coordinates
y	Transverse deflection
Y_i	Krulov–Duncan functions
Z_m, Z_β, Z_k	Impedance of the mass, damper and stiffness
Z, Y	Impedance and admittance, $Z = P/v, Y = v/P$
δ	Dirac delta function
δ_{ik}	Unit displacement
λ	Frequency parameter, $\lambda^4 EI = ml^4 \omega^2$
μ, β	Damping coefficients
ξ	Dimensionless coordinate, $\xi = x/l$
v	Velocity
ρ, m	Density of material and mass per unit length, $m = \rho A/g$
σ, ε	Stress and strain
φ, N, B	Linear operators of differential equations, boundary and initial conditions
ψ	Bending slope
ω	Natural frequency, $\omega^2 = \lambda^4 EI / ml^4$
$(\cdot) = \frac{d}{dx}$	Differentiation with respect to space coordinate
$(\cdot) = \frac{d}{dt}$	Differentiation with respect to time

3.1 MATHEMATICAL MODELS OF TRANSVERSAL VIBRATIONS OF UNIFORM BEAMS

The differential equations of free transverse vibrations and the equations for the normal functions of uniform beams according to different theories are listed in Table 3.1.

Different mathematical models take into account the following effects: the Bress–Timoshenko theory—bending, shear deformation and rotary inertia and their joint contribution; the Love theory—bending, individual contributions of shear deformation and rotary inertia; the Rayleigh theory—bending and shear; and the Bernoulli–Euler theory—bending only.

The natural frequency of vibration equals

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$$

where λ is the frequency parameter.

TABLE 3.1 Mathematical models of transverse vibration of uniform beams according to different theories

Theory	Differential equation	Equation for normal functions (The prime denotes differentiation with respect to $\zeta = x/l$)
Bernoulli–Euler	Bending without rotary inertia and shear $EI \frac{\partial^4 y}{\partial x^4} + m \frac{\partial^2 y}{\partial t^2} = 0$	$X^{IV} - \lambda^4 X = 0$
Rayleigh ($s \ll r$)	Bending with shear $EI \frac{\partial^4 y}{\partial x^4} + m \frac{\partial^2 y}{\partial t^2} - \frac{\gamma I}{g} \frac{\partial^4 y}{\partial x^2 \partial t^2} = 0$	$X^{IV} + \lambda^4 r^2 X'' - \lambda^4 X = 0$
Love complete model ($\lambda^4 r^2 s^2 \ll 1$)	Bending with rotary inertia and shear $EI \frac{\partial^4 y}{\partial x^4} + m \frac{\partial^2 y}{\partial t^2} - \left(\frac{\gamma I}{g} + \frac{EI\gamma}{gkG} \right) \frac{\partial^4 y}{\partial x^2 \partial t^2} = 0$	$X^{IV} + \lambda^4 (r^2 + s^2) X'' - \lambda^4 X = 0$
Love truncated model ($r \ll s$)	Bending with rotary inertia, shear and their mutual effects $EI \frac{\partial^4 y}{\partial x^4} + m \frac{\partial^2 y}{\partial t^2} - \frac{EI\gamma}{gkG} \frac{\partial^4 y}{\partial x^2 \partial t^2} = 0$	$X^{IV} + \lambda^4 s^2 X'' - \lambda^4 X = 0$
Bress–Timoshenko	Bending with rotary inertia, shear and their mutual effects $EI \frac{\partial^4 y}{\partial x^4} + m \frac{\partial^2 y}{\partial t^2} - \left(\frac{\gamma I}{g} + \frac{EI\gamma}{gkG} \right) \frac{\partial^4 y}{\partial x^2 \partial t^2} + \frac{\gamma I}{g} \frac{\gamma}{kgG} \frac{\partial^4 y}{\partial t^4} = 0$ $EI \frac{\partial^4 \psi}{\partial x^4} + m \frac{\partial^2 \psi}{\partial t^2} - \left(\frac{\gamma I}{g} + \frac{EI\gamma}{gkG} \right) \frac{\partial^4 \psi}{\partial x^2 \partial t^2} + \frac{\gamma I}{g} \frac{\gamma}{kgG} \frac{\partial^4 \psi}{\partial t^4} = 0$	$X^{IV} + \lambda^4 (r^2 + s^2) X'' - \lambda^4 (1 - \lambda^4 r^2 s^2) X = 0$

Dimensionless parameters r and s are

$$r^2 = \frac{I}{Al^2}, \quad s^2 = \frac{EI}{kAGl^2}$$

where r is the dimensionless radius of gyration, G is the modulus of rigidity, and k is the shear factor, $m = \rho A$, l is the length of the beam.

3.1.1 Bernoulli–Euler theory

Presented below are differential equations of the transverse vibration of non-uniformly thin beams under different conditions. A mathematical model takes into account the effect of longitudinal tensile or compressive force, and different types of elastic foundation.

1. Simplest Case. The design diagram of an elementary part of the Bernoulli–Euler beam is presented in Fig. 3.1.

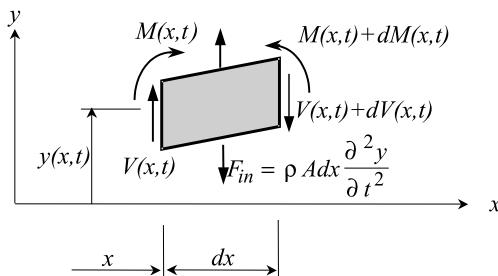

FIGURE 3.1. Notation and geometry of an element of the Bernoulli–Euler beam.

The differential equation of the transverse vibration of the thin beam is

$$\frac{\partial^2}{\partial x^2} \left[EI(x) \frac{\partial^2 y}{\partial x^2} \right] + \rho A \frac{\partial^2 y}{\partial t^2} = 0 \quad (3.1)$$

The slope, bending moment and shear force are

$$\theta = \frac{\partial y}{\partial x}, \quad M = EI \frac{\partial^2 y}{\partial x^2}, \quad V = -\frac{\partial}{\partial x} \left(EI(x) \frac{\partial^2 y}{\partial x^2} \right)$$

If a deformable system has certain specific conditions, such as a beam on an elastic foundation, a beam under axial force, etc, then additional terms must be included in the differential equation of vibration. Various effects and their corresponding differential equations for Bernoulli–Euler beams are presented in Table 3.2. These data allow us to take into account not only different effects but also to combine them to form differential equations for different beam theories.

Example. Form the differential equation of a transverse vibration of a non-uniform beam. The ends of the beam are shifted. Take into account the effect of axial force and the one-parametrical Winkler foundation with viscous damping.

TABLE 3.2 Mathematical models of transverse vibration of non-uniform Bernoulli–Euler beams

Effect	Conditions	Differential equation of transverse vibration (Bernoulli–Euler model, $EI \neq \text{const}$)	Comments
Axial force	Ends are shifted; axial force is compressive	$\frac{\partial^2}{\partial x^2} \left[EI(x) \frac{\partial^2 y}{\partial x^2} \right] + N \frac{\partial^2 y}{\partial x^2} + \rho A \frac{\partial^2 y}{\partial t^2} = 0$	Force N is constant or not, but does not depend on $y(x, t)$; system is linear
Axial force	Ends are shifted; axial force is tensile	$\frac{\partial^2}{\partial x^2} \left[EI(x) \frac{\partial^2 y}{\partial x^2} \right] - N \frac{\partial^2 y}{\partial x^2} + \rho A \frac{\partial^2 y}{\partial t^2} = 0$	Force N is constant or not, but does not depend on $y(x, t)$; system is linear
Axial force	Ends do not shift	$\frac{\partial^2}{\partial x^2} \left[EI(x) \frac{\partial^2 y}{\partial x^2} \right] - N(y) \frac{\partial^2 y}{\partial x^2} + \rho A \frac{\partial^2 y}{\partial t^2} = 0$ $N(y) = \frac{1}{2I_0} \int_{I_0}^y EI(x) \left(\frac{\partial y}{\partial x} \right)^2 dx$	Force N is a result of vibrations, so N depends on $y(x, t)$ – case of a statically nonlinear system (see Chapter 14)
Elastic Foundation	Winkler foundation. One stiffness characteristic	$\frac{\partial^2}{\partial x^2} \left[EI(x) \frac{\partial^2 y}{\partial x^2} \right] + k_{tr}y + \rho A \frac{\partial^2 y}{\partial t^2} = 0$	Reaction of the foundation $R(x) = k_{tr}y$
Elastic Foundation	Pasternak foundation. Two stiffness characteristics	$\frac{\partial^2}{\partial x^2} \left[EI(x) \frac{\partial^2 y}{\partial x^2} \right] + k_{tr}y - k_{rot} \frac{\partial^2 y}{\partial x^2} + \rho A \frac{\partial^2 y}{\partial t^2} = 0$	k_{tr} is translational stiffness coefficient Reaction of the foundation $R(x) = k_{tr}y - k_{rot} \frac{\partial^2 y}{\partial x^2}$
Elastic Foundation	Pasternak foundation. Three stiffness characteristics	$\frac{\partial^2}{\partial x^2} \left[EI(x) \frac{\partial^2 y}{\partial x^2} \right] + k_{tr}y - k_{rot} \frac{\partial^2 y}{\partial x^2} + \beta \frac{\partial y}{\partial t} + \rho A \frac{\partial^2 y}{\partial t^2} = 0$	k_{rot} is rotational stiffness coefficient Foundation with viscous damping Reaction of the foundation $R(x) = k_{tr}y - k_{rot} \frac{\partial^2 y}{\partial x^2} + \beta \frac{\partial y}{\partial t}$

Solution. The differential equation may be formed by the combination of different effects

$$\frac{\partial}{\partial x^2} \left[EI(x) \frac{\partial^2 y}{\partial x^2} \right] \pm N \frac{\partial^2 y}{\partial x^2} + k(x)y + \beta \frac{\partial y}{\partial t} + \rho A(x) \frac{\partial^2 y}{\partial t^2} = 0$$

Other models

1. *Visco-elastic beam.* External damping of the beam may be represented by distributed viscous damping dashpots with a damping constant $c(x)$ per unit length (Humar, 1990). In addition, the material of the beam obeys the stress-strain relationship

$$\sigma = E\varepsilon + \mu E \frac{\partial \varepsilon}{\partial t}$$

In this case, the differential equation of the transverse vibration of the beam may be presented in the form

$$\frac{\partial^2}{\partial x^2} \left(EI(x) \frac{\partial^2 y}{\partial x^2} \right) + \frac{\partial^2}{\partial x^2} \left[\mu I(x) \frac{\partial^3 y}{\partial t \partial x^2} \right] + c(x) \frac{\partial y}{\partial t} + \rho A(x) \frac{\partial^2 y}{\partial t^2} = 0$$

2. Different models of transverse vibrations of beams are presented in Chapter 14.

3.2 BOUNDARY CONDITIONS

The classical boundary condition takes into account only the shape of the beam deflection curve at the boundaries. The non-classical boundary conditions take into account the shape deflection curve and the additional mass, the damper, as well as the translational and rotational springs at the boundaries.

The classical boundary conditions for the transversal vibration of a beam are presented in Table 3.3.

The non-classical boundary conditions for the transversal vibration of a beam are presented in Table 3.4.

Example. Form the boundary condition at $x = 0$ for the transverse vibration of the beam shown in Fig. 3.2(a). Parameters k_1 , and β_1 are the stiffness and damper of the translational spring, k_3 and β_3 are stiffness and damper of the rotational spring (dampers β_1 and β_3 are not shown); m and J are the mass and moment of inertia of the mass.

Solution. Elastic force R in the transversal spring, and elastic moment M in the rotational spring are

$$R = k_1 y + \beta_1 \frac{\partial y}{\partial t}, \quad M = k_3 \theta + \beta_3 \frac{\partial \theta}{\partial t}$$

where y and $\theta = (\partial y / \partial x)$ are the linear deflection and slope at $x = 0$.

TABLE 3.3 Classical boundary conditions for transverse vibration of beams

Boundary conditions	At left end ($x = 0$) (the boundary conditions at the right end are not shown)	At right end ($x = l$) (the boundary conditions at the left end are not shown)
Clamped end ($y = 0, \theta = 0$)	 $y = 0; \frac{\partial y}{\partial x} = 0$	 $y = 0; \frac{\partial y}{\partial x} = 0$
Pinned end ($y = 0, M = 0$)	 $y = 0; EI \frac{\partial^2 y}{\partial x^2} = 0$	 $y = 0; EI \frac{\partial^2 y}{\partial x^2} = 0$
Free end ($V = 0, M = 0$)	 $\frac{\partial}{\partial x} \left(EI \frac{\partial^2 y}{\partial x^2} \right) = 0; EI \frac{\partial^2 y}{\partial x^2} = 0$	 $\frac{\partial}{\partial x} \left(EI \frac{\partial^2 y}{\partial x^2} \right) = 0; EI \frac{\partial^2 y}{\partial x^2} = 0$
Sliding end ($V = 0, \theta = 0$)	 $\frac{\partial}{\partial x} \left(EI \frac{\partial^2 y}{\partial x^2} \right) = 0; \frac{\partial y}{\partial x} = 0$	 $\frac{\partial}{\partial x} \left(EI \frac{\partial^2 y}{\partial x^2} \right) = 0; \frac{\partial y}{\partial x} = 0$

Notation

y and θ are the transversal deflection and slope;
 M and V are the bending moment and shear force.

Boundary conditions may be obtained by using Table 3.4:

$$\begin{aligned} \frac{\partial}{\partial x} \left(EI \frac{\partial^2 y}{\partial x^2} \right) - k_1 y - \beta_1 \frac{\partial y}{\partial t} &= M \frac{\partial^2 y}{\partial t^2} \\ EI \frac{\partial^2 y}{\partial x^2} - k_3 \frac{\partial y}{\partial x} - \beta_3 \frac{\partial^2 y}{\partial x \partial t} &= J \frac{\partial^3 y}{\partial x \partial t^2} \end{aligned}$$

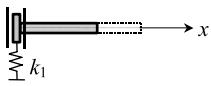

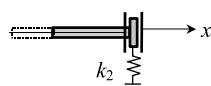

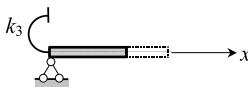

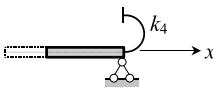

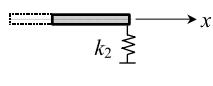

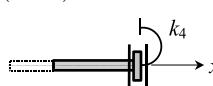

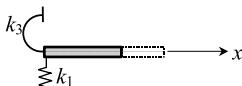

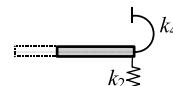

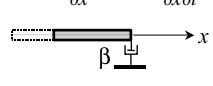

Example. Form the boundary condition beam shown in Figs 3.2(b) and 3.2(c).

Solution

Case (b)

$$\begin{aligned} y(0, t) &= 0, \quad \frac{\partial y}{\partial x}(0, t) = 0 \\ -EI \frac{\partial^2 y}{\partial x^2}(l, t) &= (J + Md^2) \frac{\partial^3 y}{\partial x \partial t^2}(l, t) + \frac{\partial^2 y}{\partial t^2}(l, t) + k_{\text{rot}} \frac{\partial y}{\partial x}(l, t) \\ EI \frac{\partial^3 y}{\partial x^3}(l, t) &= M \frac{\partial^2 y}{\partial t^2}(l, t) + Md \frac{\partial^3 y}{\partial x \partial t^2}(l, t) \end{aligned}$$

TABLE 3.4 Non-classical boundary conditions for transverse vibration of beams

Boundary conditions	At left end ($x = 0$)	At right end ($x = l$)
Sliding end with translational spring		
Pinned end with torsional spring		
Free end with translational spring		
Sliding end with torsional spring		
Elastic clamped end		
Concentrated mass		
Concentrated damper		

Parameters k_1 , and k_2 are stiffnesses of translational springs; k_3 and k_4 are the stiffnesses of rotational springs; M and J are the lumped mass and the moment of inertia of the mass.

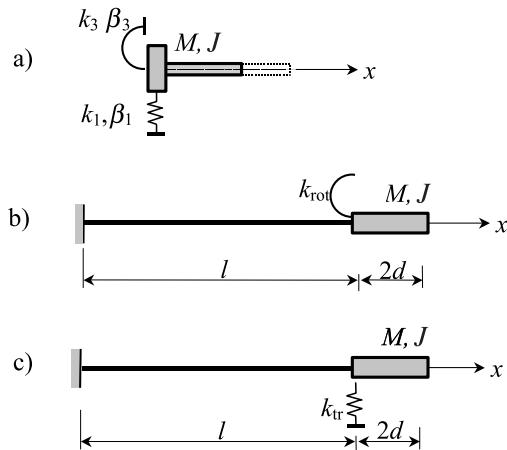

FIGURE 3.2. Nonclassical boundary condition. Beam with mass and with transitional and rotational springs and dampers (a), Beam with a heavy tip body and with a rotational spring (b) and a translational spring (c).

Case (c)

$$\begin{aligned} y(0, t) &= 0, \quad \frac{\partial y}{\partial x}(0, t) = 0 \\ -EI \frac{\partial^2 y}{\partial x^2}(l, t) &= (J + Md^2) \frac{\partial^3 y}{\partial x \partial t^2}(l, t) + Md \frac{\partial^2 y}{\partial t^2}(l, t) \\ EI \frac{\partial^3 y}{\partial x^3}(l, t) &= M \frac{\partial^2 y}{\partial t^2}(l, t) + Md \frac{\partial^3 y}{\partial x \partial t^2}(l, t) + k_{\text{tr}}y(l, t) \end{aligned}$$

The frequency equations for cases (b) and (c) are presented in Sections 7.11.2 and 7.11.3, respectively.

3.3 COMPATIBILITY CONDITIONS

Table 3.5 contains compatibility conditions between two beam segments.

Table 3.6 contains compatibility conditions between two elements of the frame with immovable joints.

3.4 ENERGY EXPRESSIONS

Kinetic energy of a system. The total kinetic energy of a system is defined as

$$T = \sum_{i=1} T_i \quad (3.2)$$

	$y_s = y_r = 0; \quad y'_s = y'_r$ $M_s = M_r$
	$y_s = y_{r-1} = y_r = 0; \quad y'_s = y'_{r-1} = y'_r$ $M_{r-1} + M_s = M_r$
	$y_{r-1} = y_r = y_{s-1} = y_s = 0; \quad y'_{s-1} = y'_s = y'_{r-1} = y'_r$ $M_{r-1} + M_s = M_{s-1} + M_r$

The expressions for kinetic energy of the transversal and rotational displacements of a beam and lumped masses are presented in Table 3.7(a).

Notation

- y total transverse deflection;
- ρ mass density of a beam material;

TABLE 3.7(a) Kinetic energy of transverse vibration of a beam

Kinetic energy of distributed masses		Kinetic energy of lumped masses	
Transversal displacement	Rotational displacement	Linear displacement	Rotational displacement
$\frac{1}{2} \int_0^l \rho A(x) \left(\frac{\partial y}{\partial t} \right)^2 dx$	$\frac{1}{2} \int_0^l \rho I(x) \left(\frac{\partial^2 y}{\partial x \partial t} - \frac{\partial \beta}{\partial t} \right)^2 dx$	$\frac{1}{2} \sum_i M_i \left(\frac{\partial y}{\partial t} \right)_{x=x_i}^2$	$\frac{1}{2} \sum_i J_i \left(\frac{\partial^2 y}{\partial x \partial t} \right)_{x=x_i}^2$

TABLE 3.7(b) Potential energy of a beam

Potential energy caused by		
Bending	Shear deformation	Two-parameter elastic foundation
$\frac{1}{2} \int_0^l EI \left(\frac{\partial^2 y}{\partial x^2} - \frac{\partial \beta}{\partial x} \right)^2 dx$	$\frac{1}{2} \int_0^l kGA\beta^2 dx$	$\frac{k_{trf}}{2} \int_0^l y^2 dx + \frac{k_{rotf}}{2} \int_0^l \left(\frac{\partial y}{\partial x} \right)^2 dx$

E modulus of elasticity;

$A(x)$ cross-sectional area;

$I(x)$ second moment of inertia of area;

J_j moment of inertia of the concentrated mass;

ψ bending slope;

β shear angle; the relationships between y , β and ψ are presented in Chapter 11.

Potential energy of a system. The total potential energy of a system is defined as

$$U = \sum_{i=1} U_i \quad (3.3)$$

The expressions for the potential energy of the beam according to the Timoshenko theory (for more details see Chapter 11) are presented in Table 3.7(b).

Notation

G modulus of rigidity;

k shear coefficient;

k_{trf} translational stiffnesses of elastic foundation;

k_{rotf} rotational stiffnesses of elastic foundation.

The potential energy accumulated in the translational and rotational springs, which are attached at $x = 0$, is calculated as

$$U_{tr} = \frac{1}{2} k_{tr} y^2(0) \quad U_{rot} = \frac{1}{2} k_{rot} \left(\frac{\partial y}{\partial x} \right)_{x=0}^2 \quad (3.4)$$

where k_{tr} and k_{rot} are the stiffnesses of the translational spring and the elastic clamped support, respectively. The energy stored in the springs is always positive and does not depend on the sign of either the force (moment) or the spring deflection (angle of rotation).

Work. Expressions for the work done by active forces are presented in Table 3.8.

TABLE 3.8 Work done by active forces

Transverse load	Axial distributed load	Axial tensile load (for compressive load negative sign)
$\frac{1}{2} \int_{x_0}^x q(x)y \, dx$	$\frac{1}{2} \int_0^l n(x) \left(\frac{\partial y}{\partial x} \right)^2 \, dx$	$\frac{N}{2} \int_0^l \left(\frac{\partial y}{\partial x} \right)^2 \, dx$

3.4.1 Rayleigh dissipative function

The real beam, transversal and rotational dampers dissipate the energy delivered to them. The dissipation function of the beam is

$$D_{beam} = \frac{1}{2} \int_0^l \beta_b EI(x) \left(\frac{\partial}{\partial t} \frac{\partial^2 y}{\partial x^2} \right)^2 \, dx \quad (3.5)$$

where β_b is the viscous coefficient of the beam material.

The dissipation functions of the transversal and rotational dampers, which are placed at $x = 0$, are

$$D_{tr} = \frac{1}{2} \beta_{tr} \frac{\partial y(0)}{\partial t}, \quad D_{rot} = \frac{1}{2} \beta_{rot} \frac{\partial^2 y(0)}{\partial x \partial t} \quad (3.6)$$

where β_{tr} and β_{rot} are coefficients of the energy dissipation in the transversal and rotational springs.

The Lagrange equation (2.8), with consideration of the energy dissipation, is presented as

$$\frac{d}{dt} \left(\frac{\partial T}{\partial \dot{q}_i} \right) - \frac{\partial T}{\partial q_i} + \frac{\partial U}{\partial q_i} + \frac{\partial D}{\partial \dot{q}_i} = Q_i, \quad i = 1, 2, 3, \dots, n \quad (3.7)$$

3.5 PROPERTIES OF EIGENFUNCTIONS

The solution of the fourth-order partial differential equation (3.1) can be obtained by using the technique of the separation of variables

$$y = X(x)T(t) \quad (3.8)$$

where $X(x)$ is a space-dependent function, and $T(t)$ is a function that depends only on time. The function $X(x)$ is called the eigenfunction.

3.5.1 Theorems about eigenfunctions

- Eigenfunctions depend on boundary conditions, the distributed mass and stiffness along a beam and do not depend on initial conditions.
- Eigenfunctions are defined with an accuracy to the arbitrary constant multiplier.
- Normalizing eigenfunctions satisfies the condition

$$\int_0^l m(x) X_j^2 \, dx = 1 \quad (3.9)$$

- The number of a nodals (the number of sign changes) of an eigenfunction of order k is equal to $k - 1$. The fundamental shape vibration has no nodals.
- Two neighbouring eigenfunctions $X_j(x)$ and $X_{j+1}(x)$ have alternating nodals.

3.5.2 Orthogonality conditions for Bernoulli-Euler beams

The property of the orthogonality of eigenfunctions can be used to obtain the solution of the differential equation of vibration in a closed form. The important definitions, such as the modal mass, modal stiffness, and modal damping coefficients may be obtained by using the orthogonality conditions of eigenfunctions.

General expression for the orthogonality condition of eigenfunctions

$$EI(X_j'')'X_k|_0^l - EI X_j'' X_k'|_0^l + \int_0^l EI X_j'' X_k'' \, dx = \omega_j^2 \int_0^l m(x) X_j X_k \, dx \quad j = 1, 2, 3, \dots \quad (3.10)$$

(a) *Classical boundary conditions.* For a beam with fixed ends, free ends, and simply supported ends, the boundary conditions are, respectively

$$\begin{aligned} X(0) &= X(l) = X'(0) = X'(l) \\ X''(0) &= X''(l) = X'''(0) = X'''(l) \\ X(0) &= X(l) = X''(0) = X''(l) \end{aligned}$$

In these cases the general expression for the orthogonality condition may be rewritten as

$$\int_0^l EI(x) X_j'' X_k'' \, dx = \omega_j^2 \int_0^l m(x) X_j X_k \, dx \quad (3.11)$$

Case $j \neq k$

- Eigenfunctions are orthogonal over the interval $(0, l)$ with respect to $m(x)$ as the weighting function

$$\int_0^l m(x) X_j(x) X_k(x) \, dx = 0$$

If lumped masses M_s on a beam have spatial coordinates x_s then

$$\int_0^l m(x)X_i(x)X_j(x)dx + \sum_s M_s X_i(x_s)X_j(x_s) = 0$$

2. The second derivatives of eigenfunctions are orthogonal with respect to $EI(x)$ as a weighting function

$$\int_0^l EI(x)X_j''X_k'' dx = 0$$

3. Because $\int_0^l [EI(x)X_j'']''X_k dx = 0$, then for a uniform beam, $EI = \text{constant}$, and eigenfunctions and their fourth derivatives are orthogonal

$$\int_0^l X_j^{IV}X_k dx = 0$$

Case $j = k$. The modal mass and modal stiffness coefficients are

$$\begin{aligned} m_j &= \int_0^l m(x)X_j^2 dx \\ k_j &= \int_0^l EI(x)(X_j'')^2 dx \end{aligned} \tag{3.12}$$

The j th natural frequency ω_j is defined as

$$\omega_j^2 = \frac{k_j}{m_j} = \frac{\int_0^l EI(x)(X_j'')^2 dx}{\int_0^l m(x)X_j^2 dx} \tag{3.13}$$

Fundamental conclusion. A mechanical system with distributed parameters may be considered as an infinite number of decoupled simple linear oscillators. The mathematical models are second-order ordinary differential equations whose solutions can be presented in a simple closed form.

Example. Derive the differential equation of a Bernoulli–Euler beam using Equation (3.7).

Solution. Transverse displacement is presented in the form of Equation (3.8)

$$y(x, t) = \sum_{k=0}^{k=\infty} X_k(x)T_k(t)$$

The kinetic energy, according to Table 3.7(a), is

$$\frac{1}{2} \int_0^l \rho A(x) \left(\frac{\partial y}{\partial t} \right)^2 dx = \frac{1}{2} \int_0^l \rho A(x) \left(\sum_{k=0}^{\infty} X_k(x) \dot{T}_k \right)^2 dx$$

Taking into account the orthogonality conditions, the kinetic energy may be rewritten in the form

$$T = \frac{1}{2} \sum_{k=0}^{k=\infty} \int_0^l \rho A(x) X_k^2(x) dx (\dot{T})^2$$

The potential energy, according to Table 3.7(b), is

$$U = \frac{1}{2} \int_0^l EI(x) \left(\frac{\partial^2 y}{\partial x^2} \right)^2 dx = \frac{1}{2} \int_0^l EI(x) \left(\sum_{k=0}^{k=\infty} X_k''(x) T_k(t) \right)^2 dx$$

Taking into account the orthogonality properties, the potential energy may be rewritten in the form

$$U = \frac{1}{2} \sum_{k=0}^{k=\infty} \int_0^l EI(x) [X_k''(x)]^2 dx T_k^2(t)$$

The dissipation function, according to Equation (3.5), is

$$D_{\text{beam}} = \frac{1}{2} \int_0^l \beta_b EI(x) \left(\frac{\partial}{\partial t} \frac{\partial^2 y}{\partial x^2} \right)^2 dx = \frac{\beta_b}{2} \int_0^l EI(x) \left(\sum_{k=0}^{k=\infty} X_k''(x) \dot{T}_k(t) \right)^2 dx$$

Taking into account the orthogonality properties, the dissipation function may be rewritten in the form

$$D = \frac{\beta_b}{2} \int_0^l \sum_{k=0}^{k=\infty} EI(x) [X_k''(x)]^2 dx \dot{T}_k^2(t)$$

Substituting expressions of U , T and D into Equation (3.7) leads to the following

$$\int_0^l \rho A(x) X_k^2(x) dx \ddot{T}_k(t) + \int_0^l EI(x) [X_k''(x)]^2 dx T_k(t) + \beta_b \int_0^l EI(x) [X_k''(x)]^2 dx \dot{T}_k(t) = 0$$

which leads to the equation corresponding to the k th mode of vibration

$$\ddot{T}(t) + 2h_k \dot{T}(t) + \omega_k^2 T(t) = 0$$

where the frequency of vibration and the damper coefficient are

$$\omega_k^2 = \frac{\int_0^l EI(x) X_k'^2 dx}{\int_0^l m(x) X_k^2 dx}, \quad h_k = \frac{\beta_b \omega_k^2}{2}$$

The expression for the square of the frequency of vibration is the Rayleigh quotient (Table 2.3); Equation (3.13).

(b) *Non-classical boundary conditions.* Consider a beam with a lumped mass, transversal and rotational springs at $x = l$ shown in Fig. 3.3.

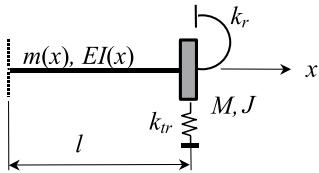

FIGURE 3.3. Non-classical boundary conditions at the right end $x = l$; boundary conditions at the left end have not been shown.

Case $j \neq k$. Orthogonality conditions over the interval $(0, l)$ are presented in the form

$$\begin{aligned} \int_0^l m(x)X_j(x)X_k(x)dx + MX_j(l)X_k(l) &= 0 \\ \int_0^l EI(x)X_j''X_k'' dx + k_{tr}X_j(l)X_k(l) + k_rX_j'(l)X_k'(l) &= 0 \end{aligned} \quad (3.14)$$

Case $j = k$. The modal mass and modal stiffness coefficients are as follows:

$$\begin{aligned} m_j &= \int_0^l m(x)X_j^2 dx + MX_j^2(l) + JX_j'^2(l) \\ k_j &= \int_0^l EI(x)(X_j'')^2 dx + k_{tr}X_j^2(l) + k_r(X_j')^2(l) \end{aligned} \quad (3.15)$$

The j th natural frequency ω_j is defined as

$$\omega_j^2 = \frac{k_j}{m_j} = \frac{\int_0^l EI(x)(X_j'')^2 dx \left[1 + \frac{k_{tr}X_j^2(l)}{S^*} + \frac{k_rX_j'^2(l)}{S^*} \right]}{\int_0^l m(x)X_j^2 dx \left[1 + \frac{MX_j^2(l)}{M^*} + \frac{JX_j'^2(l)}{M^*} \right]} \quad (3.16)$$

where the mass and stiffness of the beam corresponding to the j th eigenform are as follows:

$$\begin{aligned} M^* &= \int_0^l m(x)X_j^2 dx \\ S^* &= \int_0^l EI(x)(X_j'')^2 dx \end{aligned} \quad (3.17)$$

Equation (3.16) is an extension of the Rayleigh quotient (Table 2.3) to the case of a non-classical boundary condition, such as elastic supports and a mass with an inertial effect under rotation.

3.6 ORTHOGONAL EIGENFUNCTIONS IN INTERVAL $\mathbf{z}_1 - \mathbf{z}_2 \left(\int_{\mathbf{z}_1}^{\mathbf{z}_2} \mathbf{X}_k^2(\xi) d\xi = 1 \right)$ (FILIPPOV, 1970)

TABLE 3.9 Fundamental functions, frequency equation and frequency parameters for beams with different boundary conditions.

3.7 MECHANICAL MODELS OF ELASTIC SYSTEMS

Mechanical chain diagrams (MCDs) are abstract models of deformable systems (DSs) with vibroprotective devices (VPDs) and consist of passive elements, such as springs, masses and dampers, which are interlinked in a definite way. The MCD and DS equivalency resides in the fact that the dynamic processes, both in the source DS and its generalized diagram, coincide. The MCDs for mechanical systems with concentrated parameters (MSCP) have been extensively studied (Lenk, 1975; Harris, 1996).

A MCD allows one to perform a complete analysis of a DS by algebraic methods and to take into account structural and parametrical changes in the DS and VPD. This analysis allows one to determine amplitude–frequency and phase–frequency characteristics; and to define the forces that arise in separate elements of the system, calculate dynamic coefficients, and so on.

The fundamental characteristics of the mechanical systems are impedance ‘force/velocity’ and admittance ‘velocity/force’. The transitional rules from a MSCP to a mechanical chain diagram have been detailed in a number of publications (Harris, 1996). The amplitude–frequency and phase–frequency characteristics for a MSCP, which are represented in the form of their equivalent MCDs, are well-known (Harris, 1996).

3.7.1 Input and transitional impedance and admittance

Figure 3.4 presents an arbitrary deformable system with distributed parameters (a beam, a plate, etc) and peculiarities (holes, ribs, non-uniform stiffness, non-classical boundary conditions, etc). The boundary condition is not shown. The system is supplied with additional vibroprotective devices of the arbitrary structure such as mass m , stiffness k and damper β with following impedances

$$\begin{aligned} Z_m(j\omega) &= j\omega m \\ Z_k(j\omega) &= k/j\omega \\ Z_\beta(j\omega) &= \beta \end{aligned} \quad (3.18)$$

or their combinations (vibro-isolators, vibro-absorbers, vibro-dampers). A concentrated harmonic force affects the system in direction 1. The impedance of additional devices is equal to $Z = U + j\omega V$ in direction 2.

Expressions for the input and transitional impedance and admittance are presented in Table 3.10. (Karnovsky and Lebed, 1986; Karnovsky *et al.*, 1994). The input characteristics are related to the case when points 1 and 2 coincide; the transitional characteristics mean that points 1 and 2 are not matches. These expressions take into account the

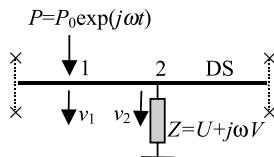

FIGURE 3.4. Deformable system with additional device with impedance $Z = U + j\omega V$.

TABLE 3.10 Input and transitional impedance and admittance for beams with additional devices

	Input (Points 1 and 2 coincide)	Transitional (Points 1 and 2 not coincide)	Comments
Impedance	$Z_{\text{inp}}(p) = \frac{P}{v}$ $= \frac{p^2 \delta_{22} V + p \delta_{22} U + 1}{p^3 DV + p^2 DU + p \delta_{11}}$	$Z_{\text{tn}}(p) = \frac{P_1}{v_2}$ $= \frac{1 + j\omega \delta_{22} Z}{j\omega \delta_{21}}$	$D = \delta_{11} \delta_{22} - \delta_{12}^2$ $p = j\omega, j = \sqrt{-1}$
Admittance	$Y_{\text{inp}}(p) = \frac{v}{p}$ $= \frac{p^3 DV + p^2 DU + p \delta_{11}}{p^2 \delta_{22} V + p \delta_{22} U + 1}$	$Z_{\text{tn}}(p) = \frac{v_2}{P_1}$ $= \frac{j\omega \delta_{21}}{1 + j\omega \delta_{22} Z}$	

properties of an arbitrary deformable system and additional passive elements mounted on the deformable system. The properties of a deformable system are represented by the unit displacements δ_{11} , δ_{12} , δ_{21} and δ_{22} . The calculations of unit displacements for bending systems are presented in Section 2.2. The properties of passive elements are represented by the real U and imaginary part V of their impedance, $Z = U + j\omega V$.

3.7.2 Mechanical two-pole terminals

'Force–velocity' and 'velocity–force' describes the dynamics of a DS in terms of the force and velocity, which are measured at the same point or at different points. The networks for characteristics Z and Y , which are presented in Table 3.10, are synthesized by the techniques of Brune, Foster, Cauer (D'Azzo and Houpis, 1966; Karnovsky, 1989).

A mechanical two-pole terminal, which realizes the input impedance $Z_{\text{inp}}(p)$ of a DS with an additional vibroprotective device of impedance $Z = U + j\omega V$ is presented in Fig. 3.5.

Mechanical two-pole terminal, which realizes the input admittance $Y_{\text{inp}}(p)$ of a DS with an additional vibroprotective device of impedance $Z = U + j\omega V$, is presented in Fig. 3.6.

The structure of the MCD does not change for different DSs. The peculiarities of the DS, such as boundary conditions, non-uniform stiffness, etc, display themselves only in the parameters of the MCD. The presence of the additional devices on the DS, such as concentrated or distributed masses, or vibroprotective devices (VPD) of any structure, is represented by additional blocks on the MCD.

Regular connections

Parallel elements: Several passive elements with impedances Z_1, Z_2, \dots are connected in parallel (Fig. 3.7(a)).

Theorem 1. *The total mechanical impedance of the parallel combination of the individual elements is equal to the sum of the partial impedances.*

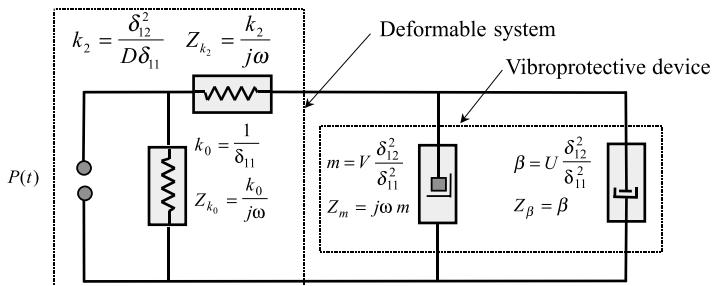

FIGURE 3.5. Network describing the input impedance $Z_{\text{imp}}(p)$ of a DS with an additional device of impedance $Z = U + j\omega V$.

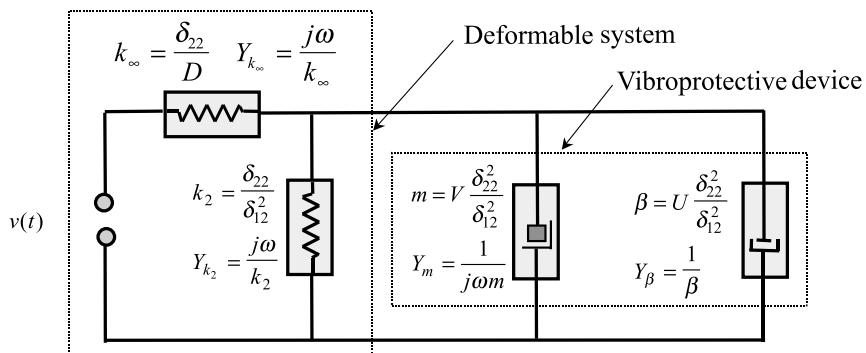

FIGURE 3.6. Network describing the input admittance $Y_{\text{imp}}(p)$ of a DS with an additional device of impedance $Z = U + j\omega V$.

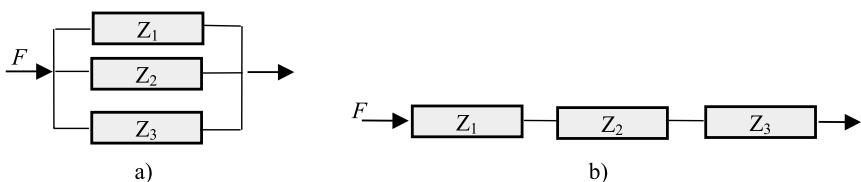

FIGURE 3.7. Regular connections: (a) parallel elements; (b) series elements.

Series elements. Several ideal passive elements with impedances Z_1, Z_2, \dots are connected in series (Fig. 3.7(b)).

Theorem 2. *The total mechanical impedance of the passive elements connected in series may be calculated from*

$$\frac{1}{Z_{str}} = \sum_1^n \frac{1}{Z_i} \quad (3.19)$$

Theorem 3. *The natural frequency of vibration of a deformable system with any additional impedance device $Z_{str} = U + j\omega V$ is*

$$\text{Im } Z_{str} = 0 \quad (3.20)$$

where Z_{str} is the impedance of the total structure.

3.7.3 Mechanical four-pole terminal

$(F_1 V_1 - F_2 V_2)$ takes into account two forces and two transversal velocities at different points 1 and 2 (Fig. 3.8).

The matrix of the condition may be presented in the form (Johnson, 1983)

$$\begin{bmatrix} v_1 \\ F_1 \end{bmatrix} = \begin{bmatrix} \frac{\sinh \lambda \cos \lambda + \cosh \lambda \sin \lambda}{\sin \lambda + \sinh \lambda} & -j \frac{\omega l^3}{EI \lambda^3} \frac{\cosh \lambda \cos \lambda - 1}{\sin \lambda + \sinh \lambda} \\ -\frac{EI \lambda^3}{j \omega l^3} \frac{2 \sinh \lambda \sin \lambda}{\sin \lambda + \sinh \lambda} & \frac{\sinh \lambda \cos \lambda + \cosh \lambda \sin \lambda}{\sin \lambda + \sinh \lambda} \end{bmatrix} \begin{bmatrix} v_2 \\ F_2 \end{bmatrix} \quad (3.21)$$

where F_1, V_1 are the shear force and linear velocity at the left end of the beam; and F_2, V_2 are at the right end. Admittances Y_a and Y_b may be presented in the form

$$Y_a = j \frac{EI \lambda^3}{\omega l^3} \frac{\sinh \lambda \cos \lambda + \cosh \lambda \sin \lambda - \sin \lambda - \sinh \lambda}{\cosh \lambda \cos \lambda - 1} \quad (3.22)$$

$$Y_b = j \frac{EI \lambda^3}{\omega l^3} \frac{\sin \lambda + \sinh \lambda}{\cosh \lambda \cos \lambda - 1}$$

The matrix equation may be easily presented in the following different forms (Karnovsky, 1989).

$$\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = A \begin{bmatrix} F_1 \\ F_2 \end{bmatrix}, \quad \begin{bmatrix} F_1 \\ F_2 \end{bmatrix} = B \begin{bmatrix} v_1 \\ v_2 \end{bmatrix}, \quad \begin{bmatrix} F_1 \\ F_2 \end{bmatrix} = C \begin{bmatrix} F_2 \\ v_1 \end{bmatrix}$$

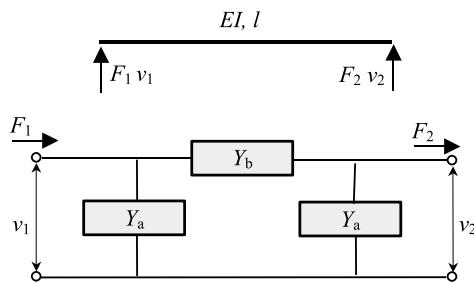

FIGURE 3.8. Mechanical four-pole terminal.

The relationships between the bending moment and shear force on the one hand and the linear and angular velocities on the other at the any point x of the infinite beam are

$$\begin{bmatrix} M(x) \\ F(x) \end{bmatrix} = [Z] \begin{bmatrix} \dot{y}(x) \\ \dot{\theta}(x) \end{bmatrix}$$

$$[Z_R] = \begin{bmatrix} EI \frac{k_b^2}{\omega} & -(1-j)EI \frac{k_b}{\omega} \\ (1+j)EI \frac{k_b^3}{\omega} & -EI \frac{k_b^2}{\omega} \end{bmatrix}, \quad [Z_L] = \begin{bmatrix} EI \frac{k_b^2}{\omega} & (1-j)EI \frac{k_b}{\omega} \\ -(1+j)EI \frac{k_b^3}{\omega} & -EI \frac{k_b^2}{\omega} \end{bmatrix}$$

$$k_b^4 = \omega^2 \frac{\rho A}{EI} \quad (3.23)$$

where Z_R and Z_L are the right- and left-wave impedance matrices respectively, k_b is the flexural wave number; and $\dot{y} = j\omega y$, $\dot{\theta} = -j\omega \theta'$ are transversal and angular velocities. The matrices Z_R and Z_L describe the process of propagation of the waves to the right and left, respectively, from a sole point force excitation (Pan and Hansen, 1993).

3.7.4 Mechanical eight-pole terminal

This takes into account the bending moment, shear force, transversal and rotational velocities at two different points (Fig. 3.9). The fundamental matrix equation of the dynamical condition of the uniform beam is (Johnson, 1983)

$$\begin{bmatrix} F_1 \\ M_1 \\ v_1 \\ \dot{\theta}_1 \end{bmatrix} = \frac{1}{2} \begin{bmatrix} \cos \lambda + \cosh \lambda & -(\sin \lambda - \sinh \lambda) \frac{\lambda}{l} \\ (\sin \lambda + \sinh \lambda) \frac{l}{\lambda} & \cos \lambda + \cosh \lambda \\ (\sin \lambda - \sinh \lambda) \frac{j\omega l^3}{EI \lambda^3} & (\cos \lambda - \cosh \lambda) \frac{j\omega l^2}{EI \lambda^2} \\ -(\cos \lambda - \cosh \lambda) \frac{j\omega l^2}{EI \lambda^2} & (\sin \lambda + \sinh \lambda) \frac{j\omega l}{EI \lambda} \end{bmatrix} \begin{bmatrix} F_2 \\ M_2 \\ v_2 \\ \dot{\theta}_2 \end{bmatrix}$$

$$\begin{bmatrix} -(\sin \lambda + \sinh \lambda) \frac{EI \lambda^3}{j\omega l^3} & -(\cos \lambda - \cosh \lambda) \frac{EI \lambda^2}{j\omega l^2} \\ (\cos \lambda - \cosh \lambda) \frac{EI \lambda^2}{j\omega l^2} & -(\sin \lambda - \sinh \lambda) \frac{EI \lambda}{j\omega l} \\ \cos \lambda + \cosh \lambda & -(\sin \lambda + \sinh \lambda) \frac{l}{\lambda} \\ (\sin \lambda - \sinh \lambda) \frac{\lambda}{l} & \cos \lambda + \cosh \lambda \end{bmatrix}$$

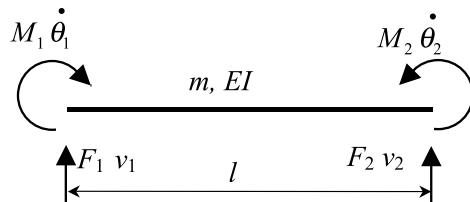

FIGURE 3.9. Notation of the beam for its presentation as a mechanical eight-pole terminal.

The dispersive relationship and frequency parameter are

$$k^4 = \frac{\rho A}{EI} \omega^2, \quad \lambda = kl \quad (3.24)$$

3.8 MODELS OF MATERIALS

Table 3.11 contains mechanical presentation and mathematical models of the visco-elastic materials. Here σ and ε are normal stress and axial strain, E is modulus of elasticity, and η is the visco-elasticity coefficient (Bland, 1960; Bolotin, Vol. 1, 1978).

The fundamental characteristics of several models are presented in Table 3.12.

Example. Derive the differential equation of the transverse vibration of the beam. The properties of the material obey the Kelvin–Voigt model

$$\sigma = E\varepsilon + \eta \frac{\partial \varepsilon}{\partial t}$$

Solution. The strain of the beam may be presented as

$$\varepsilon = \frac{z}{\rho} = -zy''$$

where ρ is the radius of curvature, and z is the distance from the neutral axis to the studied fibre of the beam.

The normal stress and bending moment are

$$\begin{aligned} \sigma &= -Ezy'' - \eta z \frac{\partial^3 y}{\partial t \partial x^2} \\ M_x &= \int_{(A)} \sigma z \, dA = -E \frac{\partial^2 y}{\partial x^2} I - \eta \frac{\partial^3 y}{\partial t \partial x^2} I \end{aligned}$$

where $I = \int_{(A)} z^2 \, dA$.

Substituting the expression for distributed load under free vibration

$$q = -m \frac{\partial^2 y}{\partial t^2}$$

TABLE 3.11 Mechanical presentation and mathematical models of visco-elastic materials

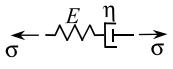

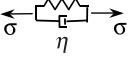

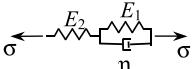

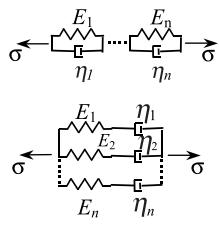

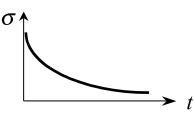

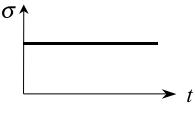

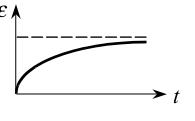

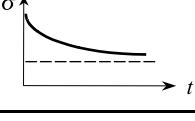

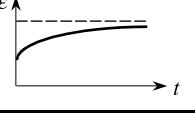

Model	Diagram	Equation
Maxwell	Relaxation medium 	$\frac{1}{E} \frac{\partial \sigma}{\partial t} + \frac{\sigma}{\eta} = \frac{\partial \varepsilon}{\partial t}$
Kelvin–Voigt	Elastic-viscous medium 	$\sigma = \left(E + \eta \frac{\partial}{\partial t} \right) \varepsilon$
Kelvin–Voigt generalized linear model		$\left(1 + \frac{E_1}{E_2} \right) \sigma + \frac{\eta}{E_2} \frac{\partial \sigma}{\partial t} = E_1 \varepsilon + \eta \frac{\partial \varepsilon}{\partial t}$
Kelvin generalized model		$\sum_{i=1}^n \left(E_i + \eta_i \frac{\partial}{\partial t} \right)^{-1} \sigma = \varepsilon$
Maxwell generalized model		$\sigma = \sum_{i=1}^n \left(\frac{1}{E_i} \frac{\partial}{\partial t} + \frac{1}{\eta_i} \right)^{-1} \times \frac{\partial \varepsilon}{\partial t}$
Three-element model of viscous-elasticity		$\frac{1}{E} \frac{\partial \sigma}{\partial t} + \frac{1}{\eta} \sigma = \tau_0 \frac{\partial^2 \varepsilon}{\partial t^2} + \frac{\partial \varepsilon}{\partial t}$

TABLE 3.12 Time dependent characteristics of visco-elastic materials

Model	Diagram $\sigma - t$ ($\varepsilon = \text{const}$)	Diagram $\varepsilon - t$ ($\sigma = \text{const}$)
Maxwell		
Kelvin–Voigt		
Kelvin–Voigt generalized linear model		

into equation $M'' = -q$ yields the differential equation

$$EI \frac{\partial^4 y}{\partial x^4} + \eta I \frac{\partial^5 y}{\partial t \partial x^4} + m \frac{\partial^2 y}{\partial t^2} = 0$$

The second term describes the dissipative properties of the beam material.

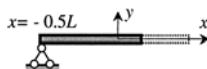

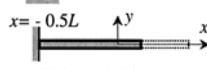

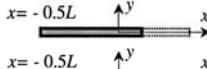

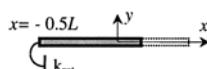

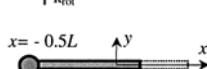

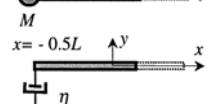

3.9 MECHANICAL IMPEDANCE OF BOUNDARY CONDITIONS

The boundary bending moment and shear force are expressed as the product of the 2×2 impedance matrix Z and a column vector containing the linear and angular velocities of the beam at the boundary

$$\begin{bmatrix} M \\ F \end{bmatrix} = [Z] \begin{bmatrix} \dot{y} \\ \dot{\theta} \end{bmatrix} \quad [Z] = \begin{bmatrix} X_{M\dot{y}} & Z_{M\dot{\theta}} \\ Z_{F\dot{y}} & Z_{F\dot{\theta}} \end{bmatrix} \quad (3.25)$$

Table 3.13 presents the impedance ‘force–linear velocity’ $Z_1 = Z_{F\dot{y}}$ and ‘moment–angular velocity’ $Z_2 = Z_{M\dot{\theta}}$ for several typical supports (Pan and Hansen, 1993). The cross terms $Z_{M\dot{y}}$ and $Z_{F\dot{\theta}}$ of the impedance matrix are zero.

TABLE 3.13 Impedance Z_1 (force–linear velocity) and Z_2 (moment–angular velocity) for different boundary conditions

	Left end condition	Boundary condition at $x = -0.5L$	Impedance Z_1 and Z_2
Pinned		$y = 0$ $y'' = 0$	$Z_1 = \infty$ $Z_2 = 0$
Fixed		$y = 0$ $y' = 0$	$Z_1 = \infty$ $Z_2 = \infty$
Free		$y'' = 0$ $y''' = 0$	$Z_1 = 0$ $Z_2 = 0$
Translational spring		$y'' = 0$ $EIy''' + k_{tr}y = 0$	$Z_1 = j \frac{k_{tr}}{\omega}$ $Z_2 = 0$
Rotational spring		$y = 0$ $EIy'' - k_{rot}y = 0$	$Z_1 = \infty$ $Z_2 = -j \frac{k_{rot}}{\omega}$
Lumped mass		$y'' = 0$ $EIy''' + M\ddot{y} = 0$	$Z_1 = -j\omega M$ $Z_2 = 0$
Dashpot		$y'' = 0$ $EIy''' + \eta\dot{y} = 0$	$Z_1 = -\eta$ $Z_2 = 0$

3.10 FUNDAMENTAL FUNCTIONS OF THE VIBRATING BEAMS

The mathematical model of transverse vibration may be presented in operation form.

The differential equation of transverse vibration of an elastic system is

$$L[y(x, t)] = f(x, t), \quad x \in D, \quad t > t_0 \quad (3.26)$$

Initial conditions

$$N[y(x, t)] = y_0(t_0, x), \quad x \in D, \quad t = t_0 \quad (3.27)$$

Boundary conditions

$$B[y(x, t)] = g(x, t), \quad x \in \partial D, \quad t > t_0 \quad (3.28)$$

where L = linear operator of differential equation;

N = linear operator of boundary conditions;

B = linear operator of initial conditions;

D = open region;

∂D = boundary points.

A *standardizing function*, $w(x, t)$, is a non-unique linear function of $f(x)$, $y_0(x)$ and $g(x)$, which transforms the mathematical model (3.26)–(3.28) with non-homogeneous initial and boundary conditions to the mathematical model with homogeneous initial and boundary conditions

$$L[y(x, t)] = w(x, t), \quad x \in D, \quad t > t_0$$

$$N[y(x, t)] = 0, \quad x \in D, \quad t = t_0$$

$$B[y(x, t)] = 0, \quad x \in \partial D, \quad t > t_0$$

Green's function (impulse transient function, influence function), $G(x, \xi, t, \tau)$, is a solution of the differential equation in the standard form. Green's function satisfies the system of equations

$$L[G(x, \xi, t, \tau)] = \delta(x - \xi, t - \tau), \quad x \in D, \quad t > t_0$$

$$N[G(x, \xi, t, \tau)] = 0, \quad x \in D, \quad t = t_0$$

$$B[G(x, \xi, t, \tau)] = 0, \quad x \in \partial D, \quad t > t_0$$

where x = point of application of disturbance force;

ξ = point of observation;

t = moment of application of disturbance force;

τ = moment of observation.

Causality principle. The Green's function

$$G(x, \xi, t, \tau) = 0, \quad x \in D, \quad \text{for } t < \tau$$

It means that any physical system cannot react to the disturbance before the moment this disturbance is applied.

The solution of system (3.26)–(3.28) is

$$y(x, t) = \int_{t_0}^t \int_D G(x, \xi, t, \tau) w(\xi, \tau) d\xi d\tau \quad (3.29)$$

This formula allows us to find the response of any linear system due to arbitrary standardizing function w , which takes into account the effect not only of internal forces $f(t)$, but also kinematic disturbance.

The *transfer function* is the Laplace transform of Green's function

$$W(x, \xi, p) = \int_0^\infty e^{-pt} G(x, \xi, t) dt, \quad p \in K \quad (3.30)$$

where K is set of a complex numbers.

3.10.1 One-span uniform Bernoulli–Euler beams

The differential equation of the transverse vibration is

$$\frac{\partial^2 y(x, t)}{\partial t^2} + a^2 \frac{\partial^4 y(x, t)}{\partial x^4} = f(x, t) \quad (3.31)$$

Initial conditions

$$y(x, 0) = y_0(x), \quad \frac{\partial y(x, 0)}{\partial t} = y_1(x) \quad (3.32)$$

Case 1. Boundary conditions

$$\begin{aligned} \frac{\partial^2 y(0, t)}{\partial x^2} &= g_1(t), \quad \frac{\partial^3 y(0, t)}{\partial x^3} = g_2(t) \\ \frac{\partial^2 y(l, t)}{\partial x^2} &= g_3(t), \quad \frac{\partial^3 y(l, t)}{\partial x^3} = g_4(t), \quad 0 \leq x \leq l, \quad a \neq 0 \end{aligned} \quad (3.33)$$

The standardizing function is a linear combination of the exciting force $f(t)$, initial conditions $y_0(t)$ and $y_1(t)$ and kinematic actions $g_i(t)$, $i = 1, \dots, 4$ (Butkovskiy, 1982).

$$\begin{aligned} w(x, t) &= f(x, t) + y_0(x)\delta'(t) + y_1(x)\delta(t) \\ &\quad - a^2\delta'(x)g_1(t) + a^2\delta(x)g_2(t) - a^2\delta'(l-x)g_3(t) - a^2\delta(x)g_4(t) \end{aligned} \quad (3.34)$$

Green's function

$$G(x, \xi, t) = \frac{4}{a} \sum_{n=1}^{\infty} \frac{X_n(x)X_n(\xi)}{k_n^2 X_n^2(l)} \sin ak_n^2 t \quad (3.35)$$

where the eigenfunction

$$X_n(x) = (\sinh k_n l - \sin k_n l)(\cosh k_n x + \cos k_n x) - (\cosh k_n l - \cos k_n l)(\sinh k_n x + \sin k_n x)$$

and eigenvalue k_n are non-negative roots of equation

$$\cosh kl \cos kl = 1$$

Transfer function

$$W(x, \xi, p) = \frac{4}{a} \sum_{n=1}^{\infty} \frac{X_n(x)X_n(\xi)}{X_n''(l)} \frac{1}{p^2 + a^2 k_n^4}, \quad p_n = \pm j a k_n^2, \quad n = 1, 2, \dots \quad (3.36)$$

Case 2. Boundary conditions

$$\begin{aligned} y(0, t) &= g_1(t), \quad \frac{\partial y(0, t)}{\partial x} = g_2(t) \\ y(l, t) &= g_3(t), \quad \frac{\partial y(l, t)}{\partial x} = g_4(t), \quad 0 \leq x \leq l, \quad a \neq 0 \end{aligned} \quad (3.37)$$

Standardizing function (Butkovskiy, 1982)

$$\begin{aligned} w(x, t) &= f(x, t) + y_0(x)\delta'(t) + y_1(x)\delta(t) \\ &\quad - a^2\delta'''(x)g_1(t) - a^2\delta''(x)g_2(t) - a^2\delta'''(l-x)g_3(t) + a^2\delta''(x)g_4(t) \end{aligned} \quad (3.38)$$

Green's function

$$G(x, \xi, t) = \frac{4}{a} \sum_{n=1}^{\infty} \frac{X_n(x)X_n(\xi)}{k_n^2 [X_n''(l)]^2} \sin a k_n^2 t \quad (3.39)$$

where

$$X_n(x) = (\sinh k_n l - \sin k_n l)(\cosh k_n x - \cos k_n x) - (\cosh k_n l - \cos k_n l)(\sinh k_n x - \sin k_n x)$$

k_n are non-negative roots of the equation $\cosh kl \cos kl = 1$.

Transfer function

$$W(x, \xi, p) = \frac{4}{a} \sum_{n=1}^{\infty} \frac{X_n(x)X_n(\xi)}{[X_n''(l)]^2} \frac{1}{p^2 + a^2 k_n^4}, \quad p_n = \pm j a k_n^2, \quad n = 1, 2, \dots \quad (3.40)$$

Case 3. Boundary conditions

$$\begin{aligned} y(0, t) &= g_1(t), \quad \frac{\partial^2 y(0, t)}{\partial x^2} = g_2(t) \\ y(l, t) &= g_3(t), \quad \frac{\partial^2 y(l, t)}{\partial x^2} = g_4(t), \quad 0 \leq x \leq l, \quad a \neq 0 \end{aligned} \quad (3.41)$$

Standardizing function (Carslaw and Jaeger, 1941; Butkovskiy, 1982)

$$\begin{aligned} w(x, t) &= f(x, t) + y_0(x)\delta'(t) + y_1(x)\delta(t) \\ &\quad + a^2\delta'''(x)g_1(t) + a^2\delta'(x)g_2(t) + a^2\delta'''(l-x)g_3(t) + a^2\delta'(x)g_4(t) \end{aligned} \quad (3.42)$$

Green's function

$$G(x, \xi, t) = \frac{2l}{a\pi^2} \sum_{n=1}^{\infty} \frac{1}{n^2} \sin \frac{n\pi x}{l} \sin \frac{n\pi x}{l} \sin \frac{an^2\pi^2}{l^2} t \quad (3.43)$$

Transfer function

$$W(x, \xi, p) = \frac{2}{l} \sum_{n=1}^{\infty} \sin \frac{n\pi x}{l} \sin \frac{n\pi \xi}{l} \frac{1}{p^2 + \frac{a^2 n^2 \pi^4}{l^4}}$$

$$W(x, \xi, p) = \frac{1}{2a^2} \left\{ \frac{\sin q(l - \xi) \sinh qx \sinh ql - \sinh q(l - \xi) \sinh qx \sin ql}{q^3 \sin ql \sinh ql} \right\}, \quad (3.44)$$

$0 \leq x \leq \xi \leq l$

$$W(x, \xi, p) = \frac{1}{2a^2} \left\{ \frac{\sin q(l - x) \sinh q\xi \sinh ql - \sinh q(l - x) \sinh q\xi \sin ql}{q^3 \sin ql \sinh ql} \right\},$$

$0 \leq \xi \leq x \leq l$

where

$$q = \sqrt{j \frac{p}{a}}, \quad p_n = \pm j \frac{an^2 \pi^2}{l^2}, \quad n = 1, 2, \dots$$

3.10.2 Clamped-free beam of non-uniform cross-sectional area

The distributed mass and the second moment of inertia are changed accordingly Equation 2.5. In this case, Green function may be obtained using Equations 2.6 and 2.7. Green's functions for two-span uniform Bernoulli–Euler beams with classical boundary conditions and intermediate elastic support are presented by Kukla (1991).

3.10.3 Two-span uniform beam with intermediate elastic support

The differential equation of the transverse vibration of a uniform beam with an intermediate elastic support is

$$m \frac{\partial^2 y(x, t)}{\partial t^2} + EI \frac{\partial^4 y(x, t)}{\partial x^4} + k(x)y(x, t) = 0, \quad k(x) = k\delta(x - x_1) \quad (3.45)$$

where δ is the Dirac delta function; k is the stiffness coefficient of the translational spring that is attached to the beam at the point x_1 (Fig. 3.10).

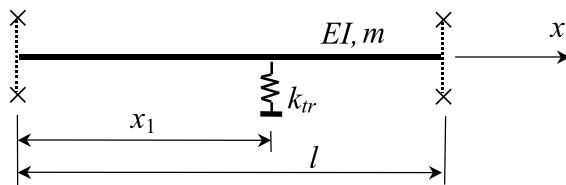

FIGURE 3.10. Two-span uniform beam with intermediate elastic support; the boundary conditions are not shown.

The frequency equation

$$2\lambda^3 g(\lambda) - \frac{kl^3}{EI} f(\xi_1, \lambda) = 0, \quad \xi_1 = \frac{x_1}{l}, \quad \lambda^4 = \frac{\rho A \omega^2 l^4}{EI} \quad (3.46)$$

Functions $g(\lambda)$ and $f(\xi_1 \lambda)$ for beams with different boundary conditions are presented in Table 3.14 (Kukla, 1991).

TABLE 3.14 Functions $g(\lambda)$ and $f(\xi_1 \lambda)$ for beams with different boundary conditions

Type beam	$g(\lambda)$	$f(\xi_1 \lambda)$
Pinned–pinned	$\sin \lambda \sinh \lambda$	$\sin \lambda \sinh \lambda \xi_1 \sinh \lambda(1 - \xi_1) - \sinh \lambda \sin \lambda \xi_1 \sin \lambda(1 - \xi_1)$
Sliding–sliding	$\sin \lambda \sinh \lambda$	$\sin \lambda \cosh \lambda \xi_1 \cos \lambda(1 - \xi_1) + \sinh \lambda \cos \lambda \xi_1 \cos \lambda(1 - \xi_1)$
Free–free	$1 - \cos \lambda \cosh \lambda$	$\begin{aligned} & \sin \lambda \cosh \lambda \xi_1 \cosh \lambda(1 - \xi_1) \\ & - \sinh \lambda \cos \lambda \xi_1 \cosh \lambda(1 - \xi_1) + \sin \lambda \xi_1 \cosh \lambda \xi_1 \\ & - \cos \lambda \xi_1 \sinh \lambda \xi_1 + \sin \lambda(1 - \xi_1) \cosh \lambda(1 - \xi_1) \\ & - \cos \lambda(1 - \xi_1) \sinh \lambda(1 - \xi_1) \end{aligned}$

Special cases

1. The beam without intermediate support ($k = 0$). In this case, the frequency equation is $g(\lambda) = 0$.
2. The beam with an intermediate rigid support ($k \rightarrow \infty$). In this case, the frequency equation is $f(\xi_1, \lambda) = 0$.

3.10.4 Static Green function for a beam with elastic support at x_1

The parameters, which define the position of the elastic support, are

$$\xi_1 = x_1/l, \quad z_1 = \lambda \xi_1 \quad \text{and} \quad z'_1 = \lambda(1 - \xi_1)$$

and the parameters, which define the position of any section along the beam, are

$$\xi = x/l, \quad z = \lambda \xi \quad \text{and} \quad z' = \lambda(1 - \xi)$$

The Green function may be formed after solution of the frequency equation (3.46).

1. Pinned–pinned beam

$$G(x_1, \xi, \lambda) = \frac{1}{2\lambda^3} \left(\frac{\sin z'_1 \sin z}{\sin \lambda} - \frac{\sinh z'_1 \sinh z}{\sinh \lambda} \right), \quad \xi < \xi_1 \quad (3.47)$$

$$G(x_1, \xi, \lambda) = \frac{1}{2\lambda^3} \left(\frac{\sin z' \sin z_1}{\sin \lambda} - \frac{\sinh z' \sinh z_1}{\sinh \lambda} \right), \quad \xi > \xi_1$$

2. Sliding–sliding beam

$$\begin{aligned} G_{sl-sl}(x_1, \xi, \lambda) &= \frac{1}{2\lambda^3} \left(\frac{\cosh z'_1 \cosh z}{\sinh \lambda} + \frac{\cos z'_1 \cos z}{\sin \lambda} \right), \quad \xi < \xi_1 \\ G_{sl-sl}(x_1, \xi, \lambda) &= \frac{1}{2\lambda^3} \left(\frac{\cosh z' \cosh z_1}{\sinh \lambda} + \frac{\cos z' \cos z_1}{\sin \lambda} \right), \quad \xi > \xi_1 \end{aligned} \quad (3.48)$$

3. Free–free beam

$$\begin{aligned} G(x_1, \xi, \lambda) &= G_{sl-sl}(x_1, \xi, \lambda) + \frac{1}{4\lambda^3} A_1 \left(\frac{\cos z}{\sin \lambda} - \frac{\cosh z}{\sinh \lambda} \right) \\ &\quad + \frac{1}{4\lambda^3} A_2 \left(\frac{\cos z'}{\sin \lambda} - \frac{\cosh z'}{\sinh \lambda} \right) \end{aligned} \quad (3.49)$$

where

$$\begin{aligned} A_1 &= [(\cos z_1 \sinh \lambda - \cosh z_1 \sin \lambda)(\cos \lambda \sinh \lambda - \cosh \lambda \sin \lambda) \\ &\quad + (\sin \lambda + \sinh \lambda)(\sin \lambda \cosh z'_1 - \cos z'_1 \sinh \lambda)] \\ &\quad \times [\sin \lambda \sinh \lambda (1 - \cos \lambda \cosh \lambda)]^{-1} \end{aligned}$$

$$\begin{aligned} A_2 &= [(\sin \lambda \cosh \lambda + \cos \lambda \sinh \lambda)(\cos z'_1 \sinh \lambda - \sin \lambda \cosh z'_1) \\ &\quad + (\sin \lambda + \sinh \lambda)(\sin \lambda \cosh z_1 - \cos z_1 \sinh \lambda)] \\ &\quad \times [\sin \lambda \sinh \lambda (1 - \cos \lambda \cosh \lambda)]^{-1} \end{aligned}$$

3.10.5 One-span sliding–sliding uniform beam

The differential equation of the transverse vibration is

$$m \frac{\partial^2 y(x, t)}{\partial t^2} + EI \frac{\partial^4 y(x, t)}{\partial x^4} = F(t) \delta(x - b) \quad (3.50)$$

where δ is the Dirac function.

Boundary conditions

$$\frac{\partial y(0, t)}{\partial x} = 0, \quad \frac{\partial^3 y(0, t)}{\partial x^3} = 0, \quad \frac{\partial y(l, t)}{\partial x} = 0, \quad \frac{\partial^3 y(l, t)}{\partial x^3} = 0 \quad (3.51)$$

Case 1. Beam with uniformly distributed mass (Fig. 3.11). Green's function $G(x, b)$ is displacement at any point x due to unit load P at the point $x = b$.

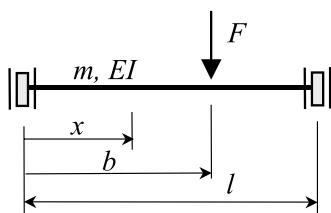

FIGURE 3.11. Sliding–sliding uniform beam carrying concentrated load.

Green's function may be presented as (Rassudov and Mjadzel, 1987)

$$\begin{aligned} G\left(\xi = \frac{x}{l}, \beta = \frac{b}{l}\right) &= Y_4(\xi - \beta)H(\xi - \beta) \\ &+ \frac{\lambda^2}{\sinh \lambda \sin \lambda} \left\{ \left[Y_4(1)Y_3(1 - \beta) - \frac{1}{\lambda^4} Y_2(1)Y_1(\xi - \beta) \right] Y_1(\xi) \right. \\ &\left. + [Y_4(1)Y_1(\xi - \beta) - Y_2(1)Y_3(1 - \beta)]Y_3(\xi) \right\} \end{aligned} \quad (3.52)$$

where H is the Heaviside function and $Y_i(i = 1, 2, 3, 4)$ are Krylov–Duncan functions (Krylov, 1936; Duncan, 1943)

$$\begin{aligned} Y_1(\lambda\xi) &= \frac{1}{2}(\cosh \lambda\xi + \cos \lambda\xi) \\ Y_2(\lambda\xi) &= \frac{1}{2\lambda}(\sinh \lambda\xi + \sin \lambda\xi) \\ Y_3(\lambda\xi) &= \frac{1}{2\lambda^2}(\cosh \lambda\xi - \cos \lambda\xi) \\ Y_4(\lambda\xi) &= \frac{1}{2\lambda^3}(\sinh \lambda\xi - \sin \lambda\xi) \end{aligned} \quad (3.53)$$

The properties of Krylov–Duncan functions will be discussed in Section 4.1.

The frequency equation and parameters λ are presented in Table 5.4.

Special cases. Green's functions $G(\xi, \beta)$ for specific parameters $\xi = x/l$, $\beta = b/l$ are presented below.

Force $F = 1$ applied at point $\beta = 0$

$$\begin{aligned} G(0, 0) &= 0.5F(\cosh \lambda \sin \lambda + \cos \lambda \sinh \lambda) \\ G(1, 0) &= 0.5F(\sin \lambda + \sinh \lambda) \\ G(\xi_0, 0) &= 0.5F[\cos \lambda(1 - \xi_0) \sin \lambda + \cos \lambda(1 - \xi_0) \sinh \lambda] \end{aligned}$$

where parameter $F = -\frac{1}{\lambda^3 \sinh \lambda \sin \lambda}$.

Force $F = 1$ applied at point $\beta = 1$

$$\begin{aligned} G(0, 1) &= 0.5F(\sin \lambda + \sinh \lambda) \\ G(1, 1) &= 0.5F(\cosh \lambda \sin \lambda + \cos \lambda \sinh \lambda) \\ G(\xi_0, 1) &= 0.5F(\cosh \lambda \xi_0 \sin \lambda + \cos \lambda \xi_0 \sinh \lambda) \end{aligned}$$

Force $F = 1$ applied at point $\beta = \xi_0$

$$G(0, \xi_0) = 0.5F[\cosh \lambda(1 - \xi_0) \sin \lambda + \cos \lambda(1 - \xi_0) \sinh \lambda]$$

$$G(1, \xi_0) = 0.5F(\cosh \lambda \xi_0 \sin \lambda + \cos \lambda \xi_0 \sinh \lambda)$$

$$G(\xi_0, \xi_0) = 0.5F[\cosh \lambda(1 - \xi_0) \cosh \lambda \xi_0 \sin \lambda + \cos \lambda(1 - \xi_0) \cos \lambda \xi_0 \cosh \lambda]$$

Case 2. Beam with distributed and lumped masses (Fig. 3.12). The mass of the system may be presented as follows:

$$m(x) = m + \sum_i m_i \delta(x - x_i)$$

where m_i is the lumped masses at $x = x_i$; and δ is the Dirac function.

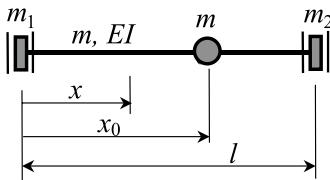

FIGURE 3.12. Sliding–sliding uniform beam with lumped masses.

Green's function

$$\begin{aligned} G(\xi_0, 0) &= -\frac{1}{\lambda^3} [H_0 C + \lambda \bar{m}_2 (AC - BD) \\ &\quad \times \{H_0^2 + H_0 \lambda [(\bar{m}_1 + \bar{m}_2)A + \bar{m}_0 E] + \lambda^2 [\bar{m}_1 \bar{m}_2 (A^2 - B^2) \\ &\quad + (\bar{m}_1 + \bar{m}_2) \bar{m}_0 A E - \bar{m}_0 (\bar{m}_1 C^2 + \bar{m}_2 D^2)]\}]^{-1} \end{aligned} \quad (3.54)$$

where the dimensionless masses and parameters are

$$\begin{aligned} \bar{m}_0 &= \frac{m_0}{M_{beam}}, \quad \bar{m}_1 = \frac{m_1}{M_{beam}}, \quad \bar{m}_2 = \frac{m_2}{M_{beam}} \\ A &= \frac{G(0, 0)}{F}, \quad B = \frac{G(1, 0)}{F}, \quad C = \frac{G(0, \xi_0)}{F}, \quad D = \frac{G(1, \xi_0)}{F}, \quad E = \frac{G(\xi_0, \xi_0)}{F} \\ H_0 &= \sinh \lambda \sin \lambda, \quad F = -\frac{1}{\lambda^3 \sinh \lambda \sin \lambda} \end{aligned}$$

FUNDAMENTAL EQUATIONS OF CLASSICAL BEAM THEORY

CHAPTER 4

SPECIAL FUNCTIONS FOR THE DYNAMICAL CALCULATION OF BEAMS AND FRAMES

Chapter 4 is devoted to special functions that are used for the dynamical calculation of different kind of beams and frames. Analytical expressions, properties and fundamental relationships, as well as tables of numerical values, are presented.

NOTATION

A	Cross-sectional area
E	Young's modulus
EI	Bending stiffness
I_z	Moment of inertia of a cross-section
$i = EI/l$	Bending stiffness per unit length
k	Frequency parameter, $k = \sqrt[4]{\frac{m\omega^2}{EI}}$
l	Length of a beam
r_{ik}	Unit reactions
S, T, U, V	Krylov–Duncan functions
t	Time
$X(x)$	Mode shape
x	Spatial coordinate
y	Transversal displacement
ρ, m	Density of material and mass per unit length
δ_i	Displacement influence functions
ξ	Dimensionless coordinate, $\xi = x/l$
λ	Frequency parameter, $\lambda = kl$
$\phi(t), \xi(t)$	Harmonic angular and linear displacement

$\phi(\lambda), \psi(\lambda)$ Zal'tsberg functions

$$\omega \quad \text{Natural frequency, } \omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$$

4.1 KRYLOV–DUNCAN FUNCTIONS

The transverse vibration of the uniform Bernoulli–Euler beam is described by the partial differential equation

$$EI \frac{\partial^4 y}{\partial x^4} + \rho A \frac{\partial^2 y}{\partial t^2} = 0 \quad (4.1)$$

where $y = y(x, t)$ = transverse displacement of a beam;

ρ = mass density;

A = cross-sectional area;

E = modulus of elasticity;

I = moment of inertia of the cross-section about the neutral axis.

Solution

1. *The travelling wave method. D'Alembert's solution.* A solution of differential equation (4.1) may be presented in the form

$$y(x, t) = A \cos(\omega t - kx)$$

where A = amplitude of vibration;

ω = frequency of free vibration;

k = propagation constant;

t = time;

x = longitudinal coordinate of the beam.

Dispersion relationship

$$\frac{\rho A}{EI} k^2 - \omega^2 = 0$$

Phase and group velocities are

$$c = \sqrt{\frac{\omega}{a}}, \quad C = 2\sqrt{\frac{\omega}{a}} \text{ where } a^2 = \frac{\rho A}{EI}$$

2. *The standing wave method. Fourier's solution.* A solution of differential equation (4.1) may be presented in the form

$$y(x, t) = X(x)T(t) \quad (4.2)$$

where $X(x)$ = space-dependent function (shape function, mode shape function, eigenfunction);

$T(t)$ = time-dependent function.

A shape function $X(x)$ depends on the boundary conditions only. After separation of variables in (4.1) the function $X(x)$ may be obtained from the equation

$$X^{IV}(x) - k^4 X(x) = 0, \text{ where } k = \sqrt[4]{\frac{m\omega^2}{EI}} \quad (4.3)$$

Note that differentiation is with respect to x , but not with respect to $\xi = x/l$, as presented in Table 3.1.

The common solution of this equation is

$$X(x) = A \cosh kx + B \sinh kx + C \cos kx + D \sin kx \quad (4.4)$$

where A , B , C and D may be calculated by using the boundary conditions (see Chapter 3.2).

The natural frequency ω of a beam is defined by

$$\omega = k^2 \sqrt{\frac{EI}{m}} = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}, \text{ where } \lambda = kl \quad (4.5)$$

4.1.1 Definitions of Krylov–Duncan functions

The common solution of differential equation (4.3) may be presented in the following form, which significantly simplifies solution of the problems

$$\begin{aligned} X(kx) &= C_1 S(kx) + C_2 T(kx) + C_3 U(kx) + C_4 V(kx) \\ S(kx) &= \frac{1}{2}(\cosh kx + \cos kx) \\ T(kx) &= \frac{1}{2}(\sinh kx + \sin kx) \\ U(kx) &= \frac{1}{2}(\cosh kx - \cos kx) \\ V(kx) &= \frac{1}{2}(\sinh kx - \sin kx) \end{aligned} \quad (4.6)$$

where

$X(kx)$ = general expression for mode shape;

$S(kx)$, $T(kx)$, $U(kx)$, $V(kx)$ = Krylov–Duncan functions (Krylov, 1936; Duncan, 1943; Babakov, 1965).

C_i = constants, expressed in terms of initial parameters, as follows

$$C_1 = X(0), \quad C_2 = \frac{1}{k}X'(0), \quad C_3 = \frac{1}{k^2}X''(0), \quad C_4 = \frac{1}{k^3}X'''(0)$$

4.1.2 Properties of Krylov–Duncan functions

Matrix representation of Krylov–Duncan functions and their derivatives at $x = 0$
 Krylov–Duncan functions and their derivatives result in the unit matrix at $x = 0$

$$\begin{array}{llll} S(0) = 1 & S'(0) = 0 & S''(0) = 0 & S'''(0) = 0 \\ T(0) = 0 & T'(0) = 1 & T''(0) = 0 & T'''(0) = 0 \\ U(0) = 0 & U'(0) = 0 & U''(0) = 1 & U'''(0) = 0 \\ V(0) = 0 & V'(0) = 0 & V''(0) = 0 & V'''(0) = 1 \end{array} \quad (4.7)$$

Higher order derivatives of Krylov–Duncan functions. Krylov–Duncan functions and their derivatives satisfy a circular relationship (see Table 4.1).

Integral relationships of Krylov–Duncan functions (Kiselev, 1980)

$$\begin{aligned} \int S(kx)dx &= \frac{1}{k}T(kx); & \int xS(kx)dx &= \frac{x}{k}T(kx) - \frac{U(kx)}{k^2} \\ \int T(kx)dx &= \frac{1}{k}U(kx); & \int xT(kx)dx &= \frac{x}{k}U(kx) - \frac{V(kx)}{k^2} \\ \int U(kx)dx &= \frac{1}{k}V(kx); & \int xU(kx)dx &= \frac{x}{k}V(kx) - \frac{S(kx)}{k^2} \\ \int V(kx)dx &= \frac{1}{k}S(kx); & \int xV(kx)dx &= \frac{x}{k}S(kx) - \frac{T(kx)}{k^2} \end{aligned} \quad (4.8)$$

Combinations of Krylov–Duncan functions

$$\begin{aligned} ST - UV &= \frac{1}{2}(\cosh kx \sin kx + \sinh kx \cos kx) \\ TU - SV &= \frac{1}{2}(\cosh kx \sin kx - \sinh kx \cos kx) \\ S^2 - U^2 \cosh kx \cos kx; \quad T^2 - V^2 &= 2(SU - V^2) = \sinh kx \sin kx \\ U^2 - TV &= \frac{1}{2}(1 - \cosh kx \cos kx); \quad S^2 - TV = \frac{1}{2}(1 + \cosh kx \cos kx) \\ T^2 - SU &= SU - V^2 = \frac{1}{2}\sinh kx \sin kx; \quad 2SU = T^2 + V^2 \end{aligned} \quad (4.9)$$

Laplace transform of Krylov–Duncan functions (Strelkov, 1964)

$$L(S) = \frac{p^3}{p^4 - k^4} \quad L(T) = \frac{kp^2}{p^4 - k^4} \quad L(U) = \frac{k^2 p}{p^4 - k^4} \quad L(V) = \frac{k^3}{p^4 - k^4} \quad (4.10)$$

TABLE 4.1 Properties of Krylov–Duncan functions

$S(x)$	Function	First derivative	Second derivative	Third derivative	Fourth derivative
$V(x)$	$S(x)$	$kV(x)$	$k^2 U(x)$	$k^3 T(x)$	$k^4 S(x)$
	$T(x)$	$kS(x)$	$k^2 V(x)$	$k^3 U(x)$	$k^4 T(x)$
	$U(x)$	$kT(x)$	$k^2 S(x)$	$k^3 V(x)$	$k^4 U(x)$
$U(x)$	$V(x)$	$kU(x)$	$k^2 T(x)$	$k^3 S(x)$	$k^4 V(x)$

Krylov–Duncan functions as a series (Ivovich, 1981)

$$\begin{aligned}
 S(kx) &= 1 + \frac{(kx)^4}{4!} + \frac{(kx)^8}{8!} + \frac{(kx)^{12}}{12!} + \dots \\
 T(kx) &= (kx) \left[1 + \frac{(kx)^4}{5!} + \frac{(kx)^8}{9!} + \dots \right] \\
 U(kx) &= (kx)^2 \left[\frac{1}{2} + \frac{(kx)^4}{6!} + \frac{(kx)^8}{10!} + \dots \right] \\
 V(kx) &= (kx)^3 \left[\frac{1}{6} + \frac{(kx)^4}{7!} + \frac{(kx)^8}{11!} + \dots \right]
 \end{aligned} \tag{4.11}$$

Krylov–Duncan functions are tabulated in Table 4.2 (Birger, Panovko, 1968).

To obtain a frequency equation using Krylov–Duncan functions, the following general algorithm is recommended.

- Step 1.* Represent the mode shape in the form that satisfies boundary conditions at $x = 0$. This expression will have only two Krylov–Duncan functions and, respectively, two constants. The decision of what Krylov–Duncan functions to use is based on Equations (4.7) and the boundary condition at $x = 0$.

Step 2. Determine constants using the boundary condition at $x = l$ and Table 4.1. Thus, the system of two homogeneous algebraic equations is obtained.

Step 3. The non-trivial solution of this system represents the frequency equation.

Detailed examples for using this algorithm are given below.

Example 1. Calculate the frequencies of vibration and find the mode shape vibration for a pinned-pinned beam. The beam has mass density ρ , length l , modulus of elasticity E , and moment of inertia of cross-sectional area I .

Solution. Boundary conditions:

At the right end ($x = l$): (3) $X(l) = 0$ (Deflection = 0);
 (4) $X''(l) = 0$ (Bending moment = 0).

At $x = 0$ the Krylov–Duncan functions and their second derivatives equal zero. According to Equations (4.7) these are $T(kx)$ and $V(kx)$ functions. Thus, the expression for the mode shape is

$$X(x) = C_2 T(kx) + C_4 V(kx)$$

Constants C_2 and C_4 are calculated from boundary conditions at $x = l$

$$X(l) = C_2 T(kl) + C_4 V(kl) = 0$$

$$X''(l) = k^2 [C_2 V(kl) + C_4 T(kl)] = 0$$

9.9	4982.14802	4982.35202	4983.03721	4982.32136
10.0	5596.19606	5506.34442	5507.03599	5506.88844

A non-trivial solution of the above system is the frequency equation

$$\begin{vmatrix} T(kl) & V(kl) \\ V(kl) & T(kl) \end{vmatrix} = 0 \rightarrow T^2(kl) - V^2(kl) = 0$$

According to Equation (4.9), this leads to $\sin kl = 0$. The roots of the equation are

$$kl = \pi, 2\pi, \dots$$

Thus, the frequencies of vibration are

$$\omega = k^2 \sqrt{\frac{EI}{m}}, \quad \omega_1 = \frac{3.1416^2}{l^2} \sqrt{\frac{EI}{m}}, \quad \omega_2 = \frac{6.2832^2}{l^2} \sqrt{\frac{EI}{m}}, \dots$$

Mode shape

$$X(x) = C_2 T(kx) + C_4 V(kx) = C_2 \left[T(k_i x) + \frac{C_4}{C_2} V(k_i x) \right]$$

Find the ratio C_4/C_2

$$\begin{aligned} X(l) &= C_2 T(kl) + C_4 V(kl) = 0 \\ X''(l) &= k^2 [C_2 V(kl) + C_4 T(kl)] = 0 \end{aligned}$$

so the ratio C_4/C_2 from first and second equations is

$$\frac{C_4}{C_2} = -\frac{T(k_i l)}{V(k_i l)} = -\frac{V(k_i l)}{T(k_i l)}$$

and the mode shape (eigenfunction) is

$$X(x) = C_2 T(kx) + C_4 V(kx) = C_2 \left[T(k_i x) - \frac{T(k_i l)}{V(k_i l)} V(k_i x) \right]$$

or

$$X(x) = C_2 U(kx) + C_4 V(kx) = C_2 \left[T(k_i x) - \frac{V(k_i l)}{T(k_i l)} V(k_i x) \right]$$

According to Table 4.2, the Krylov–Duncan functions

$$T(\pi) = V(\pi), \quad T(2\pi) = V(2\pi), \dots$$

so the mode shape is

$$X(x) = C_2 [T(k_i x) - V(k_i x)]$$

Example 2. Calculate the frequencies of vibration and find the mode of shape vibration for a clamped–free beam.

Solution. The boundary conditions are as follows:

At the left end ($x = 0$): (1) $X(0) = 0$ (Deflection = 0)

(2) $X''(0) = 0$ (Slope = 0)

At the right end ($x = l$): (3) $X''(l) = 0$ (Bending moment = 0)

(4) $X'''(l) = 0$ (Shear force = 0)

At the left end ($x = 0$), the Krylov–Duncan functions and their first derivatives equal zero. These are $U(kx)$ and $V(kx)$ functions. Thus, the expression for mode shape is

$$X(x) = C_3 U(kx) + C_4 V(kx)$$

Constants C_3 and C_4 are calculated from boundary conditions at $x = l$:

$$X''(l) = k^2 [C_3 S(kl) + C_4 T(kl)] = 0$$

$$X'''(l) = k^3 [C_3 V(kl) + C_4 S(kl)] = 0$$

A non-trivial solution of the above system is the frequency equation

$$\begin{vmatrix} S(kl) & T(kl) \\ V(kl) & S(kl) \end{vmatrix} = 0 \rightarrow S^2(kl) - V(kl)T(kl) = 0$$

According to Equation (4.9) this leads to

$$\cosh kl \cos kl + 1 = 0$$

The roots of the frequency equation are

$$kl = 1.8754, 4.694, 7.855, 10.996, \dots$$

Thus, the frequencies of vibration are

$$\omega = k^2 \sqrt{\frac{EI}{m}}, \quad \omega_1 = \frac{1.875^2}{l^2} \sqrt{\frac{EI}{m}}, \quad \omega_2 = \frac{4.694^2}{l^2} \sqrt{\frac{EI}{m}}, \dots$$

Mode shape

$$X(x) = C_3 U(kx) + C_4 V(kx) = C_3 \left[U(k_i x) + \frac{C_4}{C_3} V(k_i x) \right]$$

The ratio C_4/C_3 may be obtained using Equation 4.7

$$\begin{aligned} X''(l) &= k^2 [C_3 S(kl) + C_4 T(kl)] = 0 \\ X'''(l) &= k^3 [C_3 V(kl) + C_4 S(kl)] = 0 \end{aligned}$$

so the ratio C_4/C_3 from first and second equations is

$$\frac{C_4}{C_3} = -\frac{S(k_i l)}{T(k_i l)} = -\frac{V(k_i l)}{S(k_i l)}$$

and the mode shape (eigenfunction) is

$$X(x) = C_3 U(kx) + C_4 V(kx) = C_3 \left[U(k_i x) - \frac{S(k_i l)}{T(k_i l)} V(k_i x) \right]$$

or

$$X(x) = C_3 U(kx) + C_4 V(kx) = C_3 \left[U(k_i x) - \frac{V(k_i l)}{S(k_i l)} V(k_i x) \right]$$

Appendix A contains eigenfunctions for one-span beams with different boundary conditions. It is assumed that the eigenfunctions are normalized, i.e.

$$\int_0^l X^2(x) dx = 1$$

Example. Find an expression for the mode shape of vibration for a uniform beam with standard boundary conditions at $x = 0$.

Solution. According to the general algorithm, relationships (4.7) and the boundary conditions (Table 3.3), the mode shape of vibration for a beam with standard boundary conditions at $x = 0$ may be presented as follows:

Type of support at left end ($x = 0$)	Boundary conditions at left end	Mode shape $X(kx)$
	$y = 0$	$C_3 U(kx) + C_4 V(kx)$
Clamped end ($y = 0, \theta = 0$)	$\frac{\partial y}{\partial x} = 0$	
	$y = 0$	$C_1 S(kx) + C_2 T(kx)$
Pinned end ($y = 0, M = 0$)	$EI \frac{\partial^2 y}{\partial x^2} = 0$	
	$\frac{\partial}{\partial x} \left(EI \frac{\partial^2 y}{\partial x^2} \right) = 0$	$C_2 T(kx) + C_3 U(kx)$
Free end ($Q = 0, M = 0$)	$EI \frac{\partial^2 y}{\partial x^2} = 0$	
	$\frac{\partial}{\partial x} \left(EI \frac{\partial^2 y}{\partial x^2} \right) = 0$	$C_1 S(kx) + C_3 U(kx)$
Sliding end ($Q = 0, \theta = 0$)	$\frac{\partial y}{\partial x} = 0$	

Two unknown constants C_i are determined using boundary condition for $x = l$.

4.1.3 State equation (Strelkov, 1964; Babakov, 1965; Pilkey, 1994)

The relationship between states of two different points, for example at $x = l$ and $x = 0$ is

$$\begin{bmatrix} y(l) \\ \theta(l) \\ M(l) \\ Q(l) \end{bmatrix} = \tilde{A} \begin{bmatrix} y(0) \\ \theta(0) \\ M(0) \\ Q(0) \end{bmatrix} \quad (4.12)$$

where y = transverse displacement of the beam;

θ = angle of rotation;

M = bending moment;

Q = shear force;

\tilde{A} = system matrix, which may be written in the form

$$\tilde{A} = \begin{bmatrix} S(kl) & \frac{1}{k} T(kl) & \frac{1}{EIk^2} U(kl) & \frac{1}{EIk^3} V(kl) \\ kV(kl) & S(kl) & \frac{1}{EIk} T(kl) & \frac{1}{EIk^2} U(kl) \\ EIk^2 U(kl) & EIkV(kl) & S(kl) & \frac{1}{k} T(kl) \\ EIk^3 T(kl) & EIk^2 U(kl) & kV(kl) & S(kl) \end{bmatrix} \quad (4.13)$$

The state equation (4.12) and the system matrix (4.13) are the fundamental relationships in the theory of the vibration of beams with a uniformly distributed mass (see the initial parameter method, Chapter 5.1).

Example. Calculate the frequencies of vibration for a free-free beam.

Solution. The state equation (4.12) for the given system may be presented as two systems

$$\begin{aligned} y(l) &= S(kl)y(0) + \frac{1}{k}T(kl)\theta(0) \\ \theta(l) &= kV(kl)y(0) + S(kl)\theta(0) \\ kU(kl)y(0) + V(kl)\theta(0) &= 0 \\ kT(kl)y(0) + U(kl)\theta(0) &= 0 \end{aligned}$$

The relationship between amplitudes at $x = 0$ and $x = l$ may be obtained from the first system.

A non-trivial solution of the second system is the frequency equation

$$\begin{vmatrix} kU(kl) & V(kl) \\ kT(kl) & U(kl) \end{vmatrix} = 0 \rightarrow U^2(kl) - V(kl)T(kl) = 0$$

According to Equations (4.9) this leads to

$$1 - \cosh kl \cos kl = 0$$

The roots of the equation are

$$0, 3.9266, 7.0685, \dots$$

Thus, the frequencies of vibration are

$$\omega_1 = 0, \omega_2 = \frac{3.9266^2}{l^2} \sqrt{\frac{EI}{m}}, \omega_3 = \frac{7.0685^2}{l^2} \sqrt{\frac{EI}{m}}, \dots$$

The frequency of vibration $\omega_1 = 0$ corresponds to the rigid body mode.

Special cases

1. *Stiffness matrix.* A stiffness matrix for a massless beam may be obtained from the system matrix (4.13). If a uniformly distributed mass approaches zero ($m \rightarrow 0$) then, according to Equation (4.3), parameter k approaches zero as well ($k \rightarrow 0$). If the functions \sin , \cos , \sinh and \cosh are approximated by polynomial series and only the first terms are taken into account, then the stiffness matrix for a massless beam becomes

$$k = \begin{bmatrix} 1 & -l & l^2/2EI & l^3/6EI \\ 0 & 1 & -l/EI & l^2/2EI \\ 0 & 0 & 1 & l \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (4.14)$$

2. *Mass matrix.* A mass matrix may be obtained from the system matrix (4.13) if the length of a distributed mass approaches zero ($l \rightarrow 0$) and the distributed mass of a beam is represented as single lumped mass ($lm \rightarrow M$). If the functions \sin , \cos , \sinh and \cosh are

approximated by polynomial series and only the first terms are taken into account, then the mass matrix becomes

$$M = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ M\omega^2 & 0 & 0 & 1 \end{bmatrix} \quad (4.15)$$

System matrix (4.13), stiffness matrix (4.14) and mass matrix (4.15) are called *transfer matrices*. Detailed information concerning transfer matrices is presented by Ivovich (1981), Pilkey (1994).

4.1.4 Relationship between frequency parameters λ for different frame elements

In the general case, all elements of a frame have different parameters m , EI and length l . This yields different frequency parameters $k = \sqrt[4]{m\omega^2/EI}$ for different elements. However, for the system as a whole, the frequency vibration ω is determined by frequency parameters k of each element as follows

$$\omega^2 = k_0^4 \frac{E_0 I_0}{m_0} = k_1^4 \frac{E_1 I_1}{m_1} \quad (4.16)$$

where m_0 , EI_0 , l_0 and k_0 are the parameters of any element, which is conditionally referred as the base element;

m_1 , EI_1 , l_1 and k_1 are the parameters of other elements of the frame.

Equation (4.16) leads to the relationship

$$k_1 = k_0 \xi_1, \text{ where } \xi_1 = \sqrt[4]{\frac{m_1 E_0 I_0}{m_0 E_1 I_1}}$$

Frequency parameter

$$\lambda_1 = k_1 l_1 = k_0 \xi_1 l_1 \frac{l_0}{l_0} = \lambda_0 \frac{l_1}{l_0} \xi_1$$

which leads to the relationship

$$\lambda_1 = \lambda_0 \frac{l_1}{l_0} \sqrt[4]{\frac{m_1 E_0 I_0}{m_0 E_1 I_1}} \quad (4.17)$$

Example. The frame with different parameters m , EI , and l is presented in Fig. 4.1. Represent the frequency parameter λ_1 of the horizontal element in terms of frequency parameter λ_0 of the vertical element.

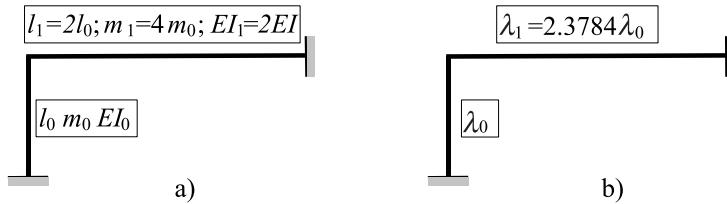

FIGURE 4.1. (a) Design diagram; (b) relationship between frequency parameters.

Solution. Let the vertical element be the base element. According to Equation (4.17) the frequency parameter of the horizontal element in terms of the frequency parameter of the vertical element is

$$\lambda_1 = \lambda_0 \frac{l_1}{l_0} \sqrt[4]{\frac{m_1 E_0 I_0}{m_0 E_1 I_1}}$$

Substituting the given data of the system (Fig. 4.1(a)) in the equation above, obtains

$$\lambda_1 = \lambda_0 \times 2 \times \sqrt[4]{4 \times \frac{1}{2}} = 2.3784\lambda_0$$

Thus, the frequency parameter \$\lambda_1\$ of the horizontal element is reduced to the frequency parameter \$\lambda_0\$ of vertical element.

The same algorithm is applicable for frames with any numbers of elements.

4.2 DYNAMICAL REACTIONS OF MASSLESS ELEMENTS WITH ONE LUMPED MASS

For the solution of the eigenvalues problem for frames with elastic uniform massless elements and a lumped mass, slope-deflection may be applicable. In this case, the dynamical reactions of the one-span beams must be used. These reactions are presented in Table 4.3. (Kiselev, 1969)

Dynamical reactions are reactions due to unit harmonic angular \$\phi(t)\$ and linear displacements \$\xi(t)\$, respectively

$$\phi(t) = 1 \times \sin \theta t, \quad \xi(t) = 1 \times \sin \theta t \quad (4.18)$$

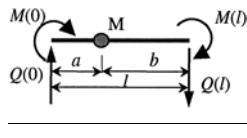

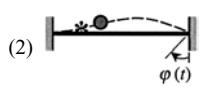

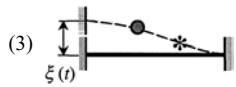

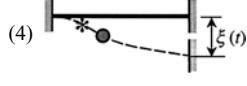

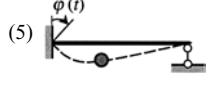

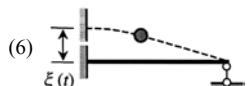

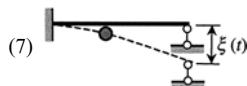

where \$\theta\$ is the frequency of harmonic displacements.

For the cases presented in Table 4.3 the frequencies of free vibrations are

$$\omega_0 = \frac{3l^3 EI}{Ma^3 b^3} \text{ for cases } 1-4 \quad (4.19)$$

$$\omega_0 = \frac{12l^3 EI}{Mb^2 a^3 (3a + 4b)} \text{ for cases } 5-7 \quad (4.20)$$

TABLE 4.3 Dynamical reactions of massless elements with one lumped mass

$M(0)$	Bending moments $M(0)$	Shear forces $Q(0)$	Functions

(5) 	$-\frac{6EI}{l^2} F_9 \mu$	$\frac{12EI}{l^3} F_{12} \mu$	$F_9 = 1 - \delta \frac{4l^2}{a(3a + 4b)}$ $F_{12} = 1 - \delta \frac{2l^2}{a^2} \frac{3a + 2b}{3a + 4b}$
(6) 	$-\frac{6EI}{l^2} F_{10} \mu$	$\frac{12EI}{l^3} F_{13} \mu$	$F_{10} = 1 - \delta \frac{2l^2}{a^2} \frac{3a + 2b}{3a + 4b}$ $F_{13} = 1 - \delta \frac{4l^3}{a^3} \frac{3a + b}{3a + 4b}$
(7) 	$-\frac{6EI}{l^2} F_{11} \mu$	$\frac{12EI}{l^3} F_{14} \mu$	$F_{11} = 1 + \delta \frac{2l^2}{b(3a + 4b)}$ $F_{14} = 1 + \delta \frac{6l^3}{ab(3a + 4b)}$

* Asterisk denotes the inflection point of the elastic curve.

Parameters μ and δ are as follows

$$\mu = \frac{1}{1 - \delta}, \quad \delta = \frac{\theta^2}{\omega_0^2}$$

Example. Find the eigenvalues of a symmetrical vibration for the frame shown in Fig. 4.2(a), assuming that all elements are massless.

Solution. The conjugate system of the frame, according to the slope and deflection method, is given in Fig. 4.2(b). Restrictions 1 and 2 prevent angular displacements, and restriction 3 prevents horizontal displacement of the frame. The basic unknowns, which correspond to the symmetrical vibrations of the framed structure, are group rotation of fixed joints 1 and 2 (Fig. 4.2(c)). The canonical equation of the slope-deflection method is

$$r_{11}Z_1 + R_{1p} = 0$$

where r_{11} = unit reaction in restriction 1 due to group rotation joint 1 through a unit angle in a clockwise direction and joint 2 in the counter-clockwise direction;

R_{1p} = reaction in the restriction 1 due to internal loads; $R_{1p} = 0$, since internal loads are absent.

The square of the frequency of vibration of a massless clamped-clamped beam with one lumped mass M according to Equation (4.19) is

$$\omega^2 = \frac{3l^2EI}{Ma^3b^3}$$

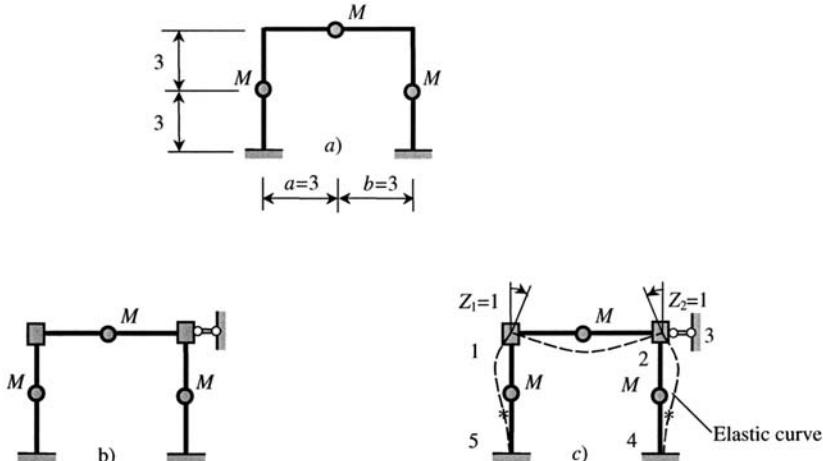

FIGURE 4.2. Design diagram and conjugate system of slope and deflection method. Z_1 and Z_2 are principal unknowns for symmetrical vibration.

If $a = b = 0.5l$, then

$$\omega^2 = \frac{192EI}{Ml^3}$$

Vertical elements 1–5. The bending moment in restriction 1, according to Table 4.3, is

$$M_{\text{vert}} = \frac{4EI}{h} F_1 \mu$$

where

$$F_1 = 1 - \frac{\theta^2}{\omega^2} \left(1 + \frac{3}{4} \times 1 \right) = 1 - \frac{7}{4} \frac{\theta^2}{\omega^2} \quad \mu = \frac{1}{1 - \frac{\theta^2}{\omega^2}}$$

thus

$$M_{\text{vert}} = \frac{4EI}{h} \left(1 - \frac{7}{4} \frac{\theta^2}{\omega^2} \right) \mu$$

Horizontal elements 1–2. The bending moment in the additional joint 1 is

$$M_{\text{horiz}} = \frac{4EI}{l} F_1 \mu - \frac{2EI}{l} F_2 \mu \quad F_1 = 1 - \frac{7}{4} \frac{\theta^2}{\omega^2}$$

$$F_2 = 1 + \frac{\delta}{2} = 1 + \frac{\theta^2}{2\omega^2} \quad M_{\text{horiz}} = \frac{2EI}{l} \left(1 - 4 \frac{\theta^2}{\omega^2} \right) \mu$$

Unit reaction (if $l = h$) is

$$\frac{r_{11}}{2} = M_{\text{vert}} + M_{\text{horiz}} = \left[\frac{4EI}{l} \left(1 - \frac{7}{4} \frac{\theta^2}{\omega^2} \right) + \frac{2EI}{l} \left(1 - 4 \frac{\theta^2}{\omega^2} \right) \right] \mu = \frac{EI}{l} \left(6 - 15 \frac{\theta^2}{\omega^2} \right) \mu$$

The frequency equation is

$$r_{11} = \frac{EI}{l} \left(6 - 15 \frac{\theta^2}{\omega^2} \right) \mu = 0$$

The square of the frequency of symmetrical vibration of the frame is

$$\theta^2 = \frac{6}{15} \omega^2 = \frac{6}{15} \frac{192EI}{Ml^3}$$

4.3 DYNAMICAL REACTIONS OF BEAMS WITH DISTRIBUTED MASSES

For the solution of the eigenvalue problem for frames with elastic uniform elements and uniformly distributed masses along the length of elements, the slope-deflection method

may be applicable (Kiselev, 1980). In this case, dynamical unit reactions of the one-span beams must be used.

Dynamical reactions are unit reactions due to unit harmonic angular $\phi(t)$ and linear $\xi(t)$ displacements according to Equation (4.18). In the case of free vibration, $\theta = \omega$, where ω is the frequency of free vibration of a system (eigenvalue). The effects of the inertial forces of distributed masses are taken into account by correction functions $\psi_i(\lambda)$.

The exact expression of the dynamical reactions may be presented using correction functions (Table 4.4) or Krylov–Duncan functions (Table 4.5). To avoid cumbersome calculation, numerical values of correction functions are presented in Table 4.6.

Approximate expression of dynamical reactions (Bolotin's functions) are presented in Table 4.7 (Bolotin, 1964; Smirnov *et al.*, 1984).

Tables 4.4–4.7 contain the following parameters:

$$\begin{aligned}\lambda &\text{ is frequency parameter, } \lambda = l \sqrt{\frac{\omega^2 m}{EI}} \\ i &\text{ is bending stiffness per unit length, } i = \frac{EI}{l}\end{aligned}$$

The equations of elastic curves of beams subjected to unit support displacement are presented in Table 4.10, later.

Example. Find eigenvalues of symmetrical vibration for the frame shown in Fig. 4.3(a), assuming that masses are distributed uniformly along the length of the elements. The length of all the elements is l ; $EI = \text{const}$.

Solution. The primary system of the frame, corresponding to the slope-deflection method is given in Fig. 4.3(b). The basic unknowns are the group of angular displacements Z_1 and Z_2 (Fig. 4.3(c)). The canonical equation is

$$r_{11}Z_1 + R_{1p} = 0$$

where $R_{1p} = 0$, since only free vibration is under investigation.

Reaction r_{11} is obtained from Table 4.4

$$\frac{r_{11}}{2} = 3i\psi_1(\lambda) + 4i\psi_2(\lambda) + 4i\psi_2(\lambda) - 2i\psi_3(\lambda)$$

or

$$r_{11} = 2[3\psi_1(\lambda) + 8\psi_2(\lambda) - 2\psi_3(\lambda)]$$

The frequency equation is

$$r_{11} = 0$$

or

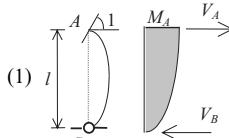

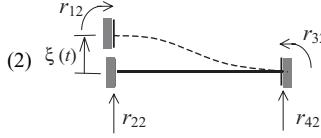

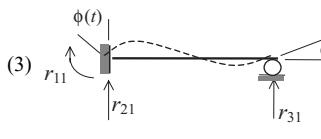

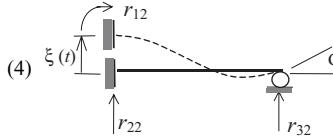

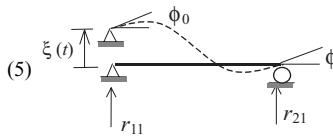

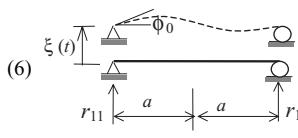

$$3\psi_1(\lambda) + 8\psi_2(\lambda) - 2\psi_3(\lambda) = 0$$

The roots of the transcendental equation are $\lambda_1 = 3.34$, $\lambda_2 = 4.25$, $\lambda_3 = 4.73, \dots$

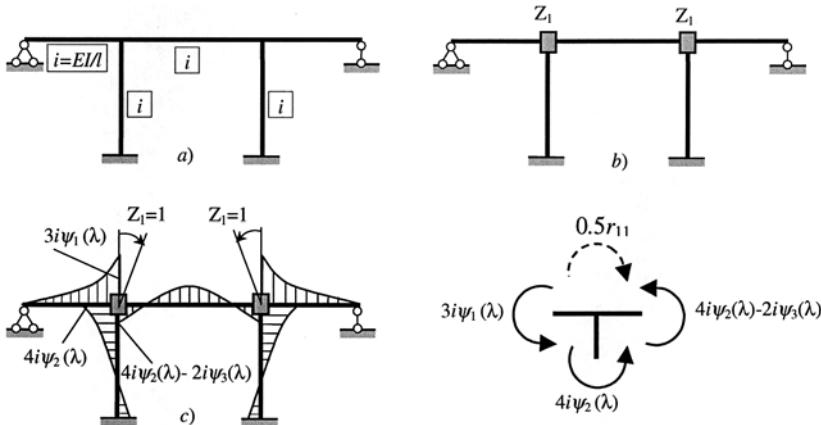

FIGURE 4.3. Design diagram, conjugate system, bending moment diagram due to a group of unit angular displacements and the free-body diagram of the joint. Frequency parameter $\lambda = l^4 \sqrt{\omega^2(m/EI)}$.

The frequencies of symmetrical vibration are

$$\begin{aligned}\omega_1 &= \left(\frac{3.34}{l}\right)^2 \sqrt{\frac{EI}{m}} \\ \omega_2 &= \left(\frac{4.25}{l}\right)^2 \sqrt{\frac{EI}{m}} \\ \omega_3 &= \left(\frac{4.73}{l}\right)^2 \sqrt{\frac{EI}{m}} \dots\end{aligned}$$

Example. Find the frequencies of free vibration for the frame shown in Fig. 4.4(a), assuming that bar masses are distributed uniformly along the length of the elements. The length of all elements is l , and $EI = \text{const}$.

Solution. The primary system of the frame, corresponding to the slope and deflection method, as well as the bending moment diagram due to the unit angular displacements Z_1 , are given in Fig. 4.4(b).

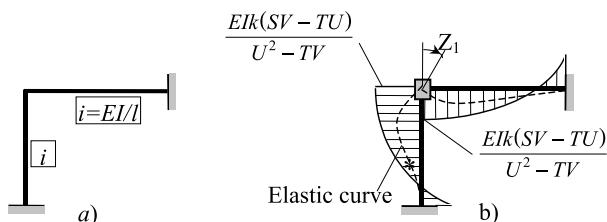

FIGURE 4.4. Design diagram, conjugate system and bending moment diagram due to unit angular displacement of joint 1.

The canonical equation of the slope-deflection method is

$$r_{11}Z_1 + R_{1p} = 0$$

where $R_{1p} = 0$ since the external forces are not considered.

Reaction r_{11} is obtained from Table 4.5

$$r_{11} = 2 \frac{EIk(SV - TU)}{U^2 - TV}$$

Frequency equation is $r_{11} = 0$, which leads to the transcendental equation

$$\tan kl = \tanh kl$$

The roots of the above equation are

$$kl = 3.926, 7.0685, \dots$$

The exact frequencies of vibration are

$$\omega_1 = \frac{3.926^2}{l^2} \sqrt{\frac{EI}{m}}, \quad \omega_2 = \frac{7.0685^2}{l^2} \sqrt{\frac{EI}{m}}, \dots$$

4.3.2 Approximate formulas (Bolotin, 1964; Smirnov et al., 1984)

Approximate expressions for the reactions of elastic uniform beams with uniformly distributed masses m due to unit angular and linear displacements of its ends, according to Equation (4.18), are presented in Table 4.7. The first term is the exact elastic reaction, due to statical unit displacement, the second term is the approximate reaction due to distributed inertial forces $mo^2y(x)$; $k = mo^2l^3$, $i = EI/l$.

The first term in the expressions for bending moment and shear force is used in statical calculation using the slope-deflection method.

Example. Determine the natural frequencies of vibration for the frame shown in Fig. 4.5(a), assuming that masses are distributed uniformly along the length of the elements. The length of all elements is l , $EI = \text{const}$.

Solution. The basic system of the frame, corresponding to the slope-deflection method, and the bending moment diagram due to unit angular displacements Z_1 are given in Fig.

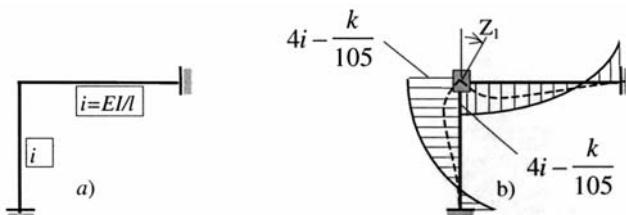

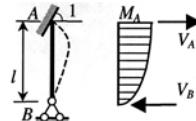

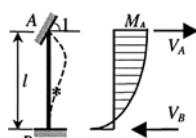

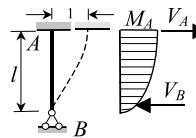

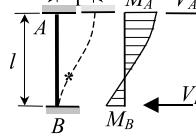

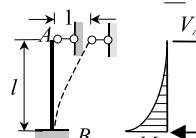

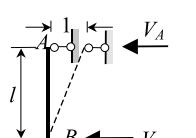

FIGURE 4.5. Design diagram, conjugate system and bending moment diagram due to unit angular displacement of joint 1.

TABLE 4.7 Approximate dynamical reactions of beams with uniformly distributed masses.

Design diagram and bending moment diagram	Bending moment	Reactions
	$M_A = 3i - \frac{2}{105}k$ $M_B = 0$	$V_A = \frac{3i}{l} - \frac{3}{35}\frac{k}{l}$ $V_B = \frac{3i}{l} + \frac{11}{280}\frac{k}{l}$
	$M_A = 4i - \frac{k}{105}$ $M_B = 2i + \frac{k}{140}$	$V_A = \frac{6i}{l} - \frac{11}{210}\frac{k}{l}$ $V_B = \frac{6i}{l} + \frac{13}{420}\frac{k}{l}$
	$M_A = \frac{3i}{l} - \frac{3}{35}\frac{k}{l}$ $M_B = 0$	$V_A = \frac{3i}{l^2} - \frac{17}{35}\frac{k}{l^2}$ $V_B = \frac{3i}{l^2} + \frac{39}{280}\frac{k}{l^2}$
	$M_A = \frac{6i}{l} - \frac{11}{210}\frac{k}{l}$ $M_B = \frac{6i}{l} + \frac{13}{420}\frac{k}{l}$	$V_A = \frac{12i}{l^2} - \frac{13}{35}\frac{k}{l^2}$ $V_B = \frac{12i}{l^2} + \frac{9}{70}\frac{k}{l^2}$
	$M_A = 0$ $M_B = \frac{3i}{l} + \frac{11}{280}\frac{k}{l}$	$V_A = \frac{3i}{l^2} - \frac{33}{140}\frac{k}{l^2}$ $V_B = \frac{3i}{l^2} + \frac{39}{280}\frac{k}{l^2}$
	$M_A = 0$ $M_B = 0$	$V_A = \frac{k}{3l^2}$ $V_B = \frac{k}{6l^2}$

4.5(b). The canonical equation of the slope-deflection method is

$$r_{11}Z_1 + R_{1p} = 0$$

where $R_{1p} = 0$, since free vibration is considered.

Reaction r_{11} is obtained from Table 4.7

$$r_{11} = 2 \left(4i - \frac{k}{105} \right)$$

The frequency equation is $r_{11} = 0$, which leads to the algebraic equation

$$4i - \frac{k}{105} = 0$$

The root of the above equation is

$$k = 4 \times 105 \frac{EI}{l} = m\omega^2 l^3$$

The approximate fundamental frequency of vibration of the frame is

$$\omega = \frac{4.527^2}{l^2} \sqrt{\frac{EI}{m}}$$

4.4 DYNAMICAL REACTIONS OF BEAMS WITH UNIFORM DISTRIBUTED MASSES AND ONE LUMPED MASS

For the solution of eigenvalue problems for frames with elastic uniform elements and uniformly distributed masses along the length of elements and one lumped mass, the slope-deflection method may be applicable. In this case, the dynamical reactions (Kiselev's functions) of one-span beams must be used. (Kiselev, 1969)

Dynamical unit reactions are reactions due to unit harmonic angular $\phi(t)$ and linear displacements $\xi(t)$, according to Equation (4.18). In the case of free vibration $\theta = \omega$, where ω is the frequency of free vibration of a deformable system. The effects of inertial forces of distributed masses and one lumped mass are taken into account by correction functions.

The exact expression of dynamical reactions for beams with different boundary conditions may be presented in terms of Krylov–Duncan functions (Table 4.8).

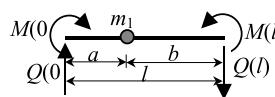

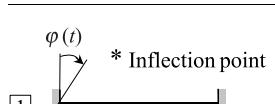

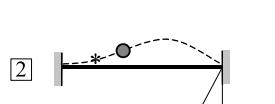

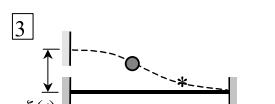

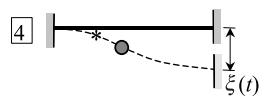

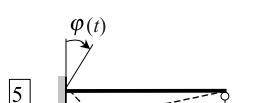

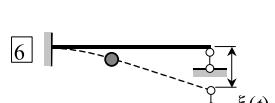

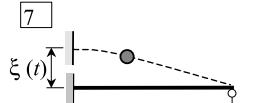

Table 4.8 contains the following parameters and functions:

$$\lambda \text{ is frequency parameter, } \lambda = l \sqrt[4]{\frac{\omega^2 m}{EI}};$$

Δ and Δ_1 are parameters that are calculated by the following formulas

$$\begin{aligned} \Delta &= U^2 - TV + \frac{m_1 \theta^2}{k^3 EI} [U_a UV_b + U_b UV_a - U_a U_b V - TV_a V_b] \\ \Delta_1 &= TU - SV + \frac{m_1 \theta^2}{k^3 EI} [TU_a V_b + UV_a T_b - SV_a V_b - T_b U_a V] \end{aligned} \quad (4.21)$$

TABLE 4.8 Exact dynamical reactions of beams with uniformly distributed masses and one lumped mass

	Bending moment $M(0)$ and shear force $Q(0)$
 [1] * Inflection point Elastic curve	$M(0) = \frac{kEI}{\Delta} \left\{ TU - SV + \frac{m_1 \theta^2}{k^3 EI} [T_a UV_b + TU_b V_a - SV_a V_b - T_a U_b V] \right\}$ $Q(0) = \frac{k^2 EI}{\Delta} \left\{ SU - T^2 + \frac{m_1 \theta^2}{k^3 EI} [T_a U_b U + SU_a V_b - T_a TV_b - TU_a U_b] \right\}$
 [2] * Deflection zero Elastic curve	$M(0) = \frac{kEI}{\Delta} \left[V + \frac{m_1 \theta^2}{k^3 EI} V_a V_b \right]$ $Q(0) = -\frac{k^2 EI}{\Delta} \left[U + \frac{m_1 \theta^2}{k^3 EI} U_a V_b \right]$
 [3] * Deflection zero Elastic curve	$M(0) = -\frac{k^2 EI}{\Delta} \left[U + \frac{m_1 \theta^2}{k^3 EI} U_b V_a \right]$ $Q(0) = \frac{k^3 EI}{\Delta} \left[T + \frac{m_1 \theta^2}{k^3 EI} U_a U_b \right]$
 [4] * Deflection zero Elastic curve	$M(0) = \frac{k^2 EI}{\Delta} \left\{ V^2 - SU + \frac{m_1 \theta^2}{k^3 EI} [S_a U_b V + V_a VV_b - S_a UV_b - SU_b V_a] \right\}$ $Q(0) = \frac{k^3 EI}{\Delta} \left\{ ST - UV + \frac{m_1 \theta^2}{k^3 EI} [S_a TV_b + SU_a U_b - S_a UU_b - U_a VV_b] \right\}$
 [5] * Deflection zero Elastic curve	$M(0) = \frac{kEI}{\Delta_1} \left\{ T^2 - V^2 + \frac{m_1 \theta^2}{k^3 EI} [T_a TV_b + T_b TV_a - T_a T_b V - VV_a V_b] \right\}$ $Q(0) = \frac{k^2 EI}{\Delta_1} \left\{ UV - ST + \frac{m_1 \theta^2}{k^3 EI} [U_a VV_b + T_a T_b U - ST_a V_b - TT_b U_a] \right\}$
 [6] * Deflection zero Elastic curve	$M(0) = -\frac{k^2 EI}{\Delta_1} \left[T + \frac{m_1 \theta^2}{k^3 EI} T_b V_a \right]$ $Q(0) = \frac{k^3 EI}{\Delta_1} \left[S + \frac{m_1 \theta^2}{k^3 EI} T_b U_a \right]$
 [7] * Deflection zero Elastic curve	$M(0) = \frac{k^2 EI}{\Delta_1} \left\{ UV - ST + \frac{m_1 \theta^2}{k^3 EI} [S_a T_b V + UV_a V_b - S_a TV_b - ST_b V_a] \right\}$ $Q(0) = \frac{k^3 EI}{\Delta_1} \left\{ S^2 - U^2 + \frac{m_1 \theta^2}{k^3 EI} [ST_b U + S_a SV_b - S_a T_b V - U_a UV_b] \right\}$

S, T, U, V = Krylov–Duncan functions that must be calculated at $x = l$; subscripts a and b indicate that these functions are calculated at $x = a$ and $x = b$, respectively.

Example. Determine the natural frequencies of antisymmetrical vibration for the frame shown in Fig. 4.6(a), assuming that the masses are distributed uniformly along the length of the elements and one concentrated mass M is attached at the middle of the horizontal element.

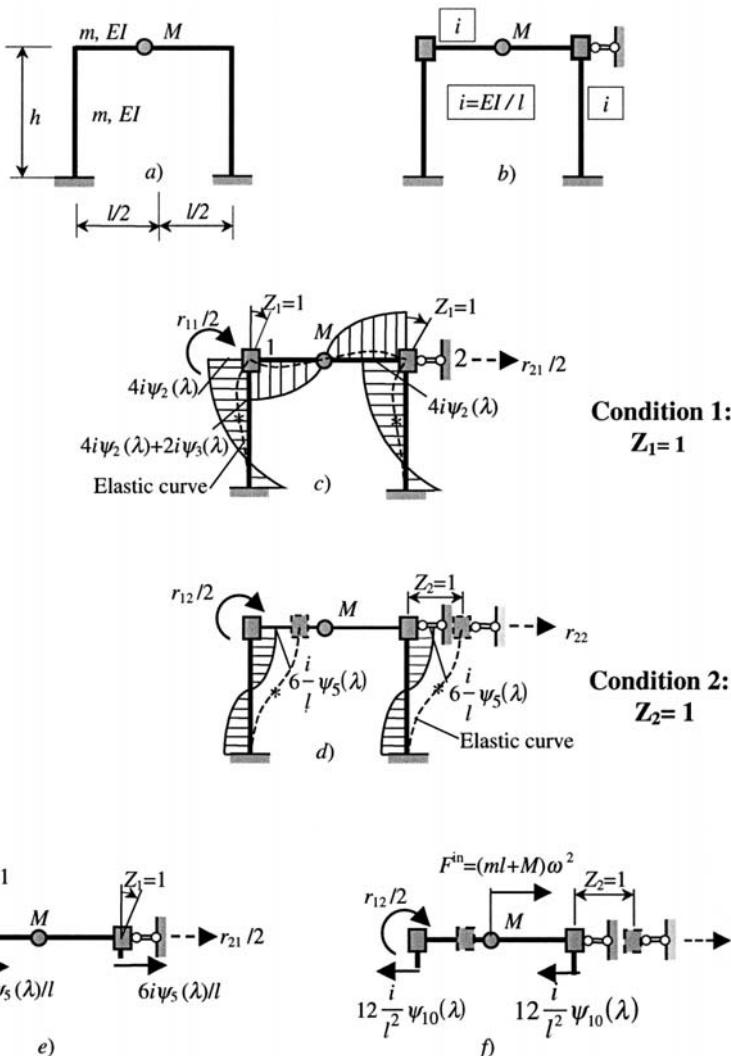

FIGURE 4.6. Design diagram, conjugate system and bending moment diagrams.

Solution. The basic system of the frame, corresponding to the slope-deflection method is given in Fig. 4.6(b). The basic unknowns are a group of angular displacements Z_1 , both in a clockwise direction, and linear displacement Z_2 (Fig. 4.6(c),(d)). The elastic curve and inflection point are presented by a dotted line and asterisk. Canonical equations are

$$\begin{aligned} r_{11}Z_1 + r_{12}Z_2 &= 0 \\ r_{21}Z_1 + r_{22}Z_2 &= 0 \end{aligned}$$

The frequency equation is

$$\begin{vmatrix} r_{11} & r_{12} \\ r_{21} & r_{22} \end{vmatrix} = 0$$

The equilibrium of joint 1 in the first and second conditions leads to

$$\begin{aligned} \frac{r_{11}}{2} &= 4i\psi_2(\lambda) + 4i\psi_2(\lambda) + 2i\psi_3(\lambda) \rightarrow r_{11} = 4i[4\psi_2(\lambda) + \psi_3(\lambda)] \\ \frac{r_{12}}{2} &= -\frac{6i}{l}\psi_5(\lambda) \rightarrow r_{12} = -\frac{12i}{l}\psi_5(\lambda) \end{aligned}$$

The equilibrium of the horizontal element in the first and second conditions (Fig. 4.6(e),(f)) leads to

$$\begin{aligned} r_{21} &= -\frac{12i}{l}\psi_5(\lambda) \\ r_{22} &= 2\frac{12i}{l^2}\psi_{10}(\lambda) - (ml + M)\omega^2 = \frac{24i}{l^2}\psi_{10}(\lambda) - \frac{\lambda^4 EI(ml + M)}{l^4 m} \end{aligned}$$

Let $M = 0.2ml$, $l = 6$ m. In this case

$$r_{22} = \frac{24i}{l^2}\psi_{10}(\lambda) - \frac{\lambda^4}{30}i$$

The frequency equation becomes

$$4i^2[4\psi_2(\lambda) + \psi_3(\lambda)]\left[\frac{24}{l^2}\psi_{10}(\lambda) - \frac{\lambda^4}{30}\right] - \left(\frac{12i}{l}\right)^2\psi_5^2(\lambda) = 0$$

The root is $\lambda = 1.74$ ($\psi_2 = 0.97834$, $\psi_3 = 1.03263$, $\psi_5 = 0.92076$, $\psi_{10} = 0.72026$).

The first frequency of antisymmetric vibration is

$$\omega = \frac{1.74^2}{6^2} \sqrt{\frac{EI}{m}} = 0.0841 \sqrt{\frac{EI}{m}}$$

4.5 FREQUENCY FUNCTIONS (HOHENEMSER-PRAGER'S FUNCTIONS)

For two-span beams with different classical and non-classical boundary conditions, Krylov-Duncan functions (4.6) may be applicable for each span. Eight unknown constants may be calculated using boundary conditions (Tables 3.3 and 3.4) and compatibility conditions (Table 3.5 and Table 3.6 for frames). This leads to systems of homogeneous algebraic equations with respect to unknown constants. A non-trivial solution of homogeneous equations is the frequency equation in the form of a determinant, which leads to a transcendental frequency equation. A special combination of the Krylov-Duncan functions

is the Hohenemser–Prager functions (Hohenemser and Prager, 1933; Anan'ev, 1946). These functions may be presented in terms of trigonometric and hyperbolic functions. These functions are

$$\begin{aligned}
 A(\lambda) &= 2[S(\lambda)T(\lambda) - U(\lambda)V(\lambda)] = \cosh \lambda \sin \lambda + \sinh \lambda \cos \lambda \\
 B(\lambda) &= 2[T(\lambda)U(\lambda) - S(\lambda)V(\lambda)] = \cosh \lambda \sin \lambda - \sinh \lambda \cos \lambda \\
 C(\lambda) &= 2 \cosh \lambda \cos \lambda = 2[S^2(\lambda) - U^2(\lambda)] = 2 \cosh \lambda \cos \lambda \\
 D(\lambda) &= 2[T(\lambda)V(\lambda) - U^2(\lambda)] = \cosh \lambda \cos \lambda - 1 \\
 S_1(\lambda) &= 2[T^2(\lambda) - V^2(\lambda)] = 2 \sinh \lambda \sin \lambda; \\
 E(\lambda) &= 2[S^2(\lambda) - T(\lambda)V(\lambda)] = \cosh \lambda \cos \lambda + 1
 \end{aligned} \tag{4.22}$$

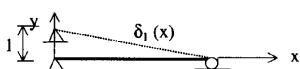

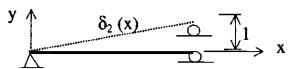

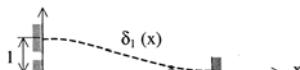

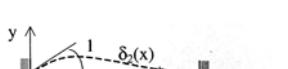

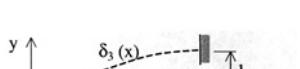

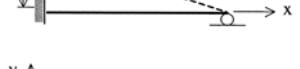

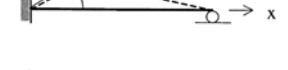

These functions occur in the frequency equations of the vibration of beams with classical and non-classical boundary conditions and therefore they are called *frequency functions*.

Hohenemser–Prager functions are tabulated in Table 4.9. Applications of Hohenemser–Prager functions are presented in Chapter 6.

4.6 DISPLACEMENT INFLUENCE FUNCTIONS

Tables 4.3, 4.4, 4.5 contain reactions of the beam due to unit angular and linear displacements of the support. The equations of elastic curves of beams subjected to unit support displacement are presented in Table 4.10 (Weaver *et al.*, 1990)

TABLE 4.10 Elastic curve functions of beams subjected to unit support displacement

	Design diagram and unit displacement of supports	Displacement functions
1(a)		$\delta_1(x) = 1 - \frac{x}{l}$
1(b)		$\delta_2(x) = \frac{x}{l}$
2(a)		$\delta_1(x) = 1 - \frac{3x^2}{l^2} + \frac{2x^3}{l^3}$
2(b)		$\delta_2(x) = x - \frac{2x^2}{l} + \frac{x^3}{l^2}$
2(c)		$\delta_3(x) = \frac{3x^2}{l^2} - \frac{2x^3}{l^3}$
2(d)		$\delta_4(x) = -\frac{x^2}{l} + \frac{x^3}{l^2}$
3(a)		$\delta_1(x) = 1 - \frac{3x^2}{2l^2} + \frac{x^3}{2l^3}$
3(b)		$\delta_2(x) = x - \frac{3x^2}{2l} + \frac{x^3}{2l^2}$
3(c)		$\delta_3(x) = \frac{3x^2}{2l^2} - \frac{x^3}{2l^3}$

CHAPTER 5

BERNOULLI-EULER UNIFORM BEAMS WITH CLASSICAL BOUNDARY CONDITIONS

This chapter focuses on Bernoulli–Euler uniform one-span beams with classical boundary conditions. Classical methods of analysis are discussed. Frequency equations and fundamental characteristics such as eigenvalues, eigenfunctions and their nodal points, as well as integrals of eigenfunctions and their derivatives, are presented.

The initial parameter method is convenient to use for the calculation of different types of uniform beams: statically determinate and indeterminate beams, one span and multispan beams, as well as beams with non-classical boundary conditions. Different cases are considered.

The force method may be applied for calculation of non-uniform beams as well as frames. Both cases are considered.

The slope-deflection method is convenient to apply for the calculation of frames with a high degree of statical indeterminacy.

NOTATION

<i>A</i>	Cross-sectional area
<i>A, B, C, E, S₁</i>	Hohenemser–Prager functions
<i>E, G</i>	Youngs' modulus and modulus of rigidity
<i>EI</i>	Bending stiffness
<i>f₁, f₂</i>	Correction functions
<i>g</i>	Acceleration due to gravity
<i>I_z</i>	Moment of inertia of a cross-section
<i>k</i>	Shear factor
<i>k_n</i>	Frequency parameter, $k_n = \sqrt{\frac{m\omega^2}{EI}}$
<i>k_{tr}, k_{rot}</i>	Translational and rotational stiffness coefficients
<i>l</i>	Length of the beam

M	Bending moment
M, J	Lumped mass and moment of inertia of the mass
Q	Shear force
r	Dimensionless radius of gyration, $r^2 A l^2 = I$
s	Dimensionless parameter, $s^2 k A G l^2 = EI$
S, T, U, V	Krylov-Duncan functions
t	Time
x	Spatial coordinate
x, y, z	Cartesian coordinates
$X(x), \psi_{(x)}$	Mode shapes
y	Transversal displacement
ζ	Dimensionless parameter
λ	Frequency parameter, $\lambda^4 EI = ml^4 \omega^2$
ξ	Dimensionless coordinate, $\xi = x/l$
ρ, m	Density of material and mass per unit length
φ, ψ	Zal'tsberg functions
ψ	Rotation of the cross-section
ω	Natural frequency, $\omega^2 = \lambda^4 EI / ml^4$

5.1 CLASSICAL METHODS OF ANALYSIS

5.1.1 Initial Parameters Method

The Initial Parameters Method is effective for dynamical calculation of beams with different boundary conditions and arbitrary peculiarities, such as elastic supports, lumped masses, etc. This method allows one to write expressions, in explicit form, for the elastic curve, slope, bending moment and shear force.

The differential equation of the transverse vibration of a beam is

$$EI \frac{\partial^4 y}{\partial x^4} + \rho A \frac{\partial^2 y}{\partial t^2} = 0 \quad (5.1)$$

The solution of this equation may be represented using initial parameters.

Initial parameters represent transverse displacement y_0 , angle of rotation φ_0 , bending moment M_0 and shear force Q_0 at $x = 0$ (Fig. 5.1).

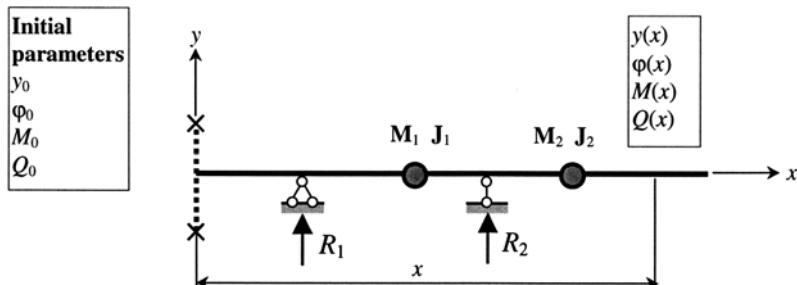

FIGURE 5.1. Design diagram of a beam and its initial parameters. The dotted line at the very left end indicates an arbitrary type of support.

State parameters $y(x)$, $\varphi(x)$, $M(x)$, $Q(x)$ at any position x may be presented in the following forms (Bezukhov *et al.*, 1969; Babakov, 1965; Ivovich, 1981)

$$\begin{aligned} y(x) = & y_0 S(kx) + \varphi_0 \frac{T(kx)}{k} + M_0 \frac{U(kx)}{k^2 EI} + Q_0 \frac{V(kx)}{k^3 EI} \\ & + \frac{1}{k^2 EI} \left(\frac{1}{k} \sum R_i V[k(x - x_i)] + \frac{\omega^2}{k} \sum \mathbf{M}_i y_i V[k(x - x_i)] - \omega^2 \sum \mathbf{J}_i \varphi_i U[k(x - x_i)] \right) \end{aligned} \quad (5.2)$$

$$\begin{aligned} \varphi(x) = & y_0 V(kx) k + \varphi_0 S(kx) + M_0 \frac{T(kx)}{EI k} + Q_0 \frac{U(kx)}{EI k^2} \\ & + \frac{1}{EI k} \left(\frac{1}{k} \sum R_i U[k(x - x_i)] + \frac{\omega^2}{k} \sum \mathbf{M}_i y_i U[k(x - x_i)] - \omega^2 \sum \mathbf{J}_i \varphi_i T[k(x - x_i)] \right) \end{aligned} \quad (5.3)$$

$$\begin{aligned} M(x) = & y_0 U(kx) EI k^2 + \varphi_0 V(kx) EI k + M_0 S(kx) + Q_0 \frac{T(kx)}{k} \\ & + \frac{1}{k} \sum R_i T[k(x - x_i)] + \frac{\omega^2}{k} \sum \mathbf{M}_i y_i T[k(x - x_i)] - \omega^2 \sum \mathbf{J}_i \varphi_i S[k(x - x_i)] \end{aligned} \quad (5.4)$$

$$\begin{aligned} Q(x) = & y_0 T(kx) EI k^3 + \varphi_0 U(kx) EI k^2 + M_0 V(kx) k + Q_0 S(kx) \\ & + \sum R_i S[k(x - x_i)] + \omega^2 \sum \mathbf{M}_i y_i S[k(x - x_i)] - \omega^2 k \sum \mathbf{J}_i \varphi_i V[k(x - x_i)] \end{aligned} \quad (5.5)$$

where

\mathbf{M}_i = lumped masses (note: M_0 = bending moment at $x = 0$)

\mathbf{J}_i = moment of inertia of a lumped mass

R_i = concentrated force (active or reactive)

x_i = distance between origin and point of application R_i or \mathbf{M}_i
 y_i, φ_i = vertical displacement and slope at point where lumped
mass \mathbf{M}_i is located

$S(x), T(x), U(x), V(x)$ = Krylov–Duncan functions (properties of these functions
are presented in Chapter 4)

Parameter k is

$$k = \sqrt[4]{\frac{m}{EI} \omega^2}; \quad kl = \sqrt[4]{\frac{m}{EI} \omega^2 l} = \lambda$$

The application of lumped mass \mathbf{M} at any point $x = a$ causes inertial force $F_{in} = \mathbf{M}\omega^2 y(a)$, which acts on the beam at $x = a$.

If the beam is supported by a transversal spring with stiffness parameter k_{tr} at any point $x = a$, then elastic force $R = k_{tr} y(a)$ must be taken into account in the above equations.

If the beam is supported by a rotational spring with stiffness parameter k_{rot} at any point $x = a$, then elastic moment $M = k_{rot} \varphi(a)$ must also be taken into account in the above equations.

The first four terms of Equations (5.2)–(5.5) may be presented in matrix form (4.12)–(4.13). The first four terms in the expression for displacement (5.2) may be presented as a series (Sekhniashvili, 1960)

$$y(x) = y_0 \left[1 + \sum_{s=1}^{\infty} \frac{(kx)^{4s}}{(4s)!} \right] + \frac{\varphi_0}{k} \sum_{s=0}^{\infty} \frac{(kx)^{4s+1}}{(4s+1)!} + \frac{M_0}{EIk^2} \sum_{s=0}^{\infty} \frac{(kx)^{4s+2}}{(4s+2)!} + \frac{Q_0}{EIk^3} \sum_{s=0}^{\infty} \frac{(kx)^{4s+3}}{(4s+3)!} \quad (5.6)$$

The expression for slope, bending moment and shear force may be presented as a series after taking higher derivatives of Equation (5.6).

In Sekhniashvili (1960), the Initial Parameters Method is modified and applied for non-uniform beams as well as Timoshenko beams.

Example. Find the frequency of vibration for a pinned-clamped beam.

Solution. The initial parameters and kinematic conditions are shown in Fig. 5.2. The unknown parameters φ_0, Q_0 may be calculated using boundary conditions at $x = l$.

Using Equations (5.2) and (5.3) of the Initial Parameters Method, the deflection and slope at $x = l$ may be presented in the form

$$\begin{aligned} y(l) &= \varphi_0 \frac{T_l}{k} + Q_0 \frac{V_l}{EIk^3} = 0 \\ \varphi(l) &= \varphi_0 S_l + Q_0 \frac{U_l}{EIk^2} = 0 \end{aligned}$$

Thus, the homogeneous system of equations is obtained. This system has a non-trivial solution if and only if the following determinant, which represents the frequency equation, is zero.

$$\begin{vmatrix} \frac{T_l}{k} & \frac{V_l}{EIk^3} \\ S_l & \frac{U_l}{EIk^2} \end{vmatrix} = 0 \rightarrow T_l U_l - S_l V_l = 0$$

According to Equation (4.9), this leads to

$$T_l U_l - S_l V_l = \cosh kl \sin kl - \sinh kl \cos kl = 0$$

or

$$\tan kl = \tanh kl$$

The roots of this equation, as well as the eigenfunction, nodal points and asymptotic eigenvalues are presented in Tables 3.9 and 5.3.

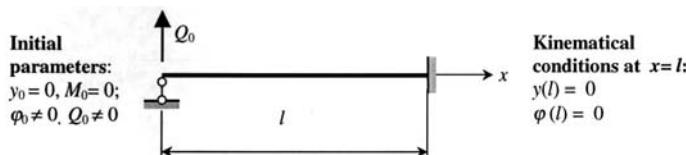

FIGURE 5.2. Design diagram of pinned-clamped beam.

Example. Find the frequency of vibration for a pinned-pinned beam with one concentrated mass M (Fig. 5.3).

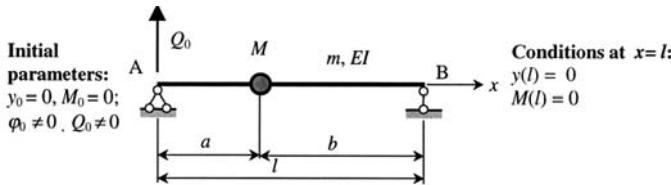

FIGURE 5.3. Design diagram of a pinned-pinned beam with one lumped mass.

Solution. The initial parameters and kinematic conditions are shown in Fig. 5.3. Unknown slope φ_0 and shear force Q_0 at $x = 0$ (point A) may be calculated using boundary conditions at $x = l$.

Displacement at $x = l$ (point B)

$$y_l = \varphi_0 \frac{T(\lambda)}{k} + Q_0 \frac{V(\lambda)}{k^3 EI} + \frac{\omega^2 M}{k^3 EI} y(a)V(kb) = 0 \quad (a)$$

Moment at $x = l$ (point B)

$$M_l = \varphi_0 V(\lambda) EI k + Q_0 \frac{T(\lambda)}{k} + \frac{\omega^2 M}{k} y(a) T(kb) = 0 \quad (b)$$

Displacement at $x = a$

$$y(a) = \varphi_0 \frac{T(ka)}{k} + Q_0 \frac{V(ka)}{EI k^3} \quad (c)$$

Substituting Equation (c) into Equations (a) and (b), the following system of two homogeneous algebraic equations with unknown initial parameters φ_0 and Q_0 is obtained

$$\begin{aligned} \varphi_0 \left[\frac{T(\lambda)}{k} + n\lambda V(kb) \frac{T(ka)}{k} \right] + Q_0 \left[\frac{V(\lambda)}{k^3 EI} + n\lambda V(kb) \frac{V(ka)}{k^3 EI} \right] &= 0 \\ \varphi_0 \left[V(\lambda) EI k + \frac{\omega^2 M}{k^2} T(ka) T(kb) \right] + Q_0 \left[\frac{T(\lambda)}{k} + \frac{n\lambda}{k} V(ka) T(kb) \right] &= 0 \end{aligned} \quad (d)$$

The trivial solution $\varphi_0 = Q_0 = 0$ of the above system implies that there is no vibration. For the non-trivial solution, the determinant of coefficients at φ_0 and Q_0 must be zero

$$\begin{bmatrix} \frac{T(\lambda)}{k} + n\lambda V(kb) \frac{T(ka)}{k} & \frac{V(\lambda)}{k^3 EI} + n\lambda V(kb) \frac{V(ka)}{k^3 EI} \\ V(\lambda) EI k + \frac{\omega^2 M}{k^2} T(ka) T(kb) & \frac{T(\lambda)}{k} + \frac{n\lambda}{k} V(ka) T(kb) \end{bmatrix} = 0$$

or

$$\begin{aligned} T^2(\lambda) - V^2(\lambda) + n\lambda T(\lambda)[V(ka)T(kb) + V(kb)T(ka)] \\ - n\lambda V(\lambda)[T(ka)T(kb) + V(kb)V(ka)] = 0 \end{aligned} \quad (e)$$

In terms of elementary functions, the frequency equation (e) may be presented in closed form

$$2\operatorname{sh}\lambda \sin \lambda + n\lambda(\sin \lambda \operatorname{sh}\xi_1 \lambda \operatorname{sh}\xi_2 \lambda - \operatorname{sh}\lambda \sin \xi_1 \lambda \sin \xi_2 \lambda) = 0$$

where

$$\frac{\omega^2 M}{k^3 EI} = n\lambda, \quad n = \frac{M}{ml}, \quad \xi_1 = \frac{a}{l}, \quad \xi_2 = \frac{b}{l} = 1 - \xi_1$$

Special case. If $\xi_1 = 0$ or $\xi_2 = 0$ (mass M is located at the support and does not influence vibration), or $M = 0$, then the frequency equation becomes $\sin \lambda = 0$ (Table 5.3, case 1).

Example. Derive the frequency equation for a uniform clamped-pinned-pinned beam with uniformly distributed masses along the beam (Fig. 5.4).

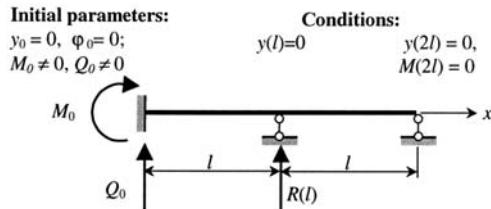

FIGURE 5.4. Design diagram and notation for clamped-pinned-pinned beam.

Solution. The initial parameters and kinematic conditions are shown in Fig. 5.4. Unknown parameters $M_0, Q_0, R(l)$ may be calculated by using boundary conditions at $x = l$ and $x = 2l$.

Using the Initial Parameters Method (Equations (5.2)–(5.5)), leads to

$$\begin{aligned} y(l) &= M_0 \frac{U(l)}{EIk^2} + Q_0 \frac{V(l)}{EIk^3} = 0 \\ y(2l) &= M_0 \frac{U(2l)}{EIk^2} + Q_0 \frac{V(2l)}{EIk^3} + \frac{1}{EIk^3} R(l)V(l) = 0 \\ M(2l) &= M_0 S(2l) + Q_0 \frac{T(2l)}{k} + \frac{1}{k} R(l)T(l) = 0 \end{aligned}$$

The non-trivial solution leads to the following frequency equation

$$\begin{vmatrix} \frac{U(l)}{EIk^2} & \frac{V(l)}{EIk^3} & 0 \\ \frac{U(2l)}{EIk^2} & \frac{V(2l)}{EIk^3} & \frac{V(l)}{EIk^3} \\ S(2l) & \frac{T(2l)}{k} & \frac{T(l)}{k} \end{vmatrix} = 0 \quad \text{or} \quad \begin{vmatrix} kU(l) & V(l) & 0 \\ kU(2l) & V(2l) & V(l) \\ kS(2l) & T(2l) & T(l) \end{vmatrix} = 0$$

which can be written as

$$U_l V_{2l} T_l + V_l^2 S_{2l} - U_l V_l T_{2l} - U_{2l} V_l T_l = 0$$

Subscripts l and $2l$ in the Krylov-Duncan functions denote that these functions are calculated at $x = l$ and $x = 2l$, respectively.

Example. Derive the frequency equation for a beam shown in Fig. 5.5.

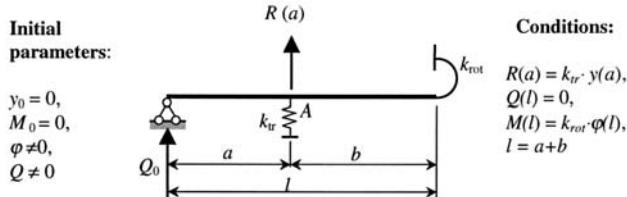

FIGURE 5.5. Design diagram of beam with elastic supports.

Solution. Initial parameters and kinematic conditions are shown in Fig. 5.5. Unknown initial parameters M_0 , Q_0 , and $R(a)$ may be calculated using boundary conditions at $x = l$ and $x = 2l$.

Using the Initial Parameters Method (Equations (5.2)–(5.5)) leads to

$$M(l) = \varphi_0 V(kl) EI k + Q_0 \frac{T(l)}{k} + \frac{1}{k} R(a) T[k(l-a)] = k_{rot} \varphi(l)$$

$$Q(l) = \varphi_0 U(l) EI k^2 + Q_0 S(l) + k_{tr} y(a) S(b) = 0$$

where

$$\varphi(l) = \varphi_0 S(l) + Q_0 \frac{U(l)}{EI k^2} + k_{tr} y(a) \frac{U(b)}{EI k^2}$$

$$y(a) = \varphi_0 \frac{T(a)}{k} + Q_0 \frac{V(a)}{EI k^3}$$

Substituting expressions $\varphi(l)$ and $y(a)$ in formulas for $M(l)$ and $Q(l)$ leads to two algebraic equations with respect to two unknowns φ_0 , Q_0 . The non-trivial solution leads to a frequency equation.

5.1.2 Force Method

Continuous beams. For dynamical calculation of multispan non-uniform beams with different stiffness and mass distribution, Three-Moment Equations (Rogers, 1959) may be used. A Three-Moment Equation establishes a relationship between moments on three consecutive supports of a beam. The physical meaning of a Three-Moment Equation is that the mutual angle of rotation on the n th support is zero. The special numbering of spans and supports is presented in Fig. 5.6.

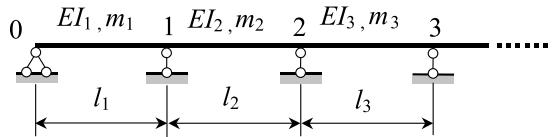

FIGURE 5.6. Notation of multispan non-uniform beam.

The Three-Moment Equation may be written in canonical form

$$\frac{l_n}{6EI_n} f_2(\lambda_n) M_{n-1} + 2 \left[\frac{l_n}{6EI_n} f_1(\lambda_n) + \frac{l_{n+1}}{6EI_{n+1}} f_1(\lambda_{n+1}) \right] M_n + \frac{l_{n+1}}{6EI_{n+1}} \cdot f_2(\lambda_{n+1}) M_{n+1} = 0 \quad (5.7)$$

where

M_n = moment on the n th support

n = numbering of a span that coincides with the numbering of a right support (counted from left to right)

$f_1(\lambda), f_2(\lambda)$ = dynamical functions

$$f_1(\lambda) = \frac{3}{2\lambda} \frac{\cosh \lambda \sin \lambda - \sinh \lambda \cos \lambda}{\sinh \lambda \sin \lambda} = \frac{3}{2\lambda} \varphi_n \quad (5.7a)$$

$$f_2(\lambda) = \frac{3}{\lambda} \frac{\sinh \lambda - \sin \lambda}{\sinh \lambda \sin \lambda} = \frac{3}{\lambda} \psi_n \quad (5.7b)$$

$$\varphi_n = \coth \lambda - \cot \lambda \quad (5.7c)$$

$$\psi_n = \csc \lambda - \operatorname{csch} \lambda \quad (5.7d)$$

where φ_n, ψ_n = Zal'tsberg functions.

Note: in Rogers (1959) coefficients $3/2\lambda$ and $3/\lambda$ (Equations (5.7a,b)) are included in functions φ_n, ψ_n .

Functions $f_1(\lambda)$ and $f_2(\lambda)$ are used for the determination of angle of rotation $y'(0)$ and shear force. The corresponding formulas are presented in Table 5.1.

The Three-Moment Equation (5.7), according to Table 5.1, may be presented in terms of Zal'tsberg functions

$$\frac{\psi_n}{i_n} M_{n-1} + \left(\frac{\varphi_n}{i_n} + \frac{\varphi_{n+1}}{i_{n+1}} \right) M_n + \frac{\psi_{n+1}}{i_{n+1}} M_{n+1} = 0, \quad i_n = \frac{EI_n}{l_n}$$

and Zal'tsberg functions may be presented in terms of Krylov-Duncan functions

$$\psi_n = 2 \frac{V(\lambda)}{T^2(\lambda) - V^2(\lambda)}, \quad \varphi_n = 2 \frac{T(\lambda)U(\lambda) - S(\lambda)V(\lambda)}{T^2(\lambda) - V^2(\lambda)}$$

Zal'tsberg functions are tabulated and presented in Table 5.2.

TABLE 5.1. Simply supported beam: angle of rotation and shear force caused by harmonic moments

Design diagram	Angle of rotation $y'(0)$	Shear force $Q(0)$
	$y'(0) = M \frac{l}{3EI} f_1(\lambda)$ $f_1(\lambda) = \frac{3(TU - SV)}{\lambda(T^2 - V^2)}$ $= \frac{3}{2} \frac{\cosh \lambda \sin \lambda - \sinh \lambda \cos \lambda}{\lambda \sinh \lambda \sin \lambda}$	$Q(0) = Mk \frac{UV - ST}{T^2 - V^2}$ $= -Mk \frac{\cosh \lambda \sin \lambda + \sinh \lambda \cos \lambda}{2 \sinh \lambda \sin \lambda}$ $k = \sqrt[4]{\frac{m\theta^2}{EI}}, \quad \lambda = kl$
	$y'(0) = M \frac{l}{6EI} f_2(\lambda)$ $f_2(\lambda) = \frac{6V}{\lambda(T^2 - V^2)} = \frac{3}{\lambda} \frac{\sinh \lambda - \sin \lambda}{\sinh \lambda \sin \lambda}$	$Q(0) = Mk \frac{T}{T^2 - V^2} = -Mk \frac{\sinh \lambda + \sin \lambda}{2 \sinh \lambda \sin \lambda}$

Applications of Zal'tsberg functions are presented in Sections 5.2, 9.3 and 9.6.

The frequency equation. After the application of Equation (5.7) to a multispan continuous beam, a system of homogeneous algebraic equations is obtained. For non-trivial solutions, the determinant of coefficients in front of M_{m-1} , M_n and M_{n+1} must be zero.

0.5π	1.09033	0.56986	π	∞	∞	1.5π	1.00016	-1.01797

It is convenient to express frequency parameters λ of any span n in terms of frequency parameter λ_0 of the very left-hand span. During the free vibration

$$\omega^2 = \frac{\lambda_0^2}{l_0^2} \sqrt{\frac{E_0 I_0}{m_0}} = \frac{\lambda_n^2}{l_n^2} \sqrt{\frac{E_n I_n}{m_n}}$$

$$\lambda_n = \lambda_0 \frac{l_n}{l_0} \sqrt[4]{\frac{m_n E_0 I_0}{m_0 E_n I_n}}$$

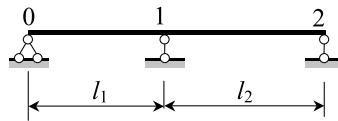

If one or both supports are not pinned but clamped, then additional spans l_0 or l_i with pinned supports must be added to replace the existing clamped support. After the Three-Moment Equation (5.7) is applied to the modified system, the length of additional spans must be considered as zero.

Special cases

1. If rigidity EI and distributed mass m are constant throughout the length of a beam, then frequency parameter $\lambda_n = \lambda_{n+1} = \lambda$.
2. If $\lambda_n = \lambda_{n+1} = \lambda$ and $l_i = \text{constant}$, then the Three-Moment Equation in terms of Krylov-Duncan functions is

$$M_{n-1}V + 2M_n(TU - SV) + M_{n+1}V = 0$$

Example. Derive the frequency equation for the following uniform beam.

Solution. For the middle support, the Three-Moment Equation is

$$M_1(t) \left[\frac{\cosh kl_1 \sin kl_1 - \sinh kl_1 \cos kl_1}{2 \sinh kl_1 \sin kl_1} + \frac{\cosh kl_2 \sin kl_2 - \sinh kl_2 \cos kl_2}{2 \sinh kl_2 \sin kl_2} \right] = 0$$

or

$$M_1(t)[\coth kl_1 - \cot kl_1 + \coth kl_2 - \cot kl_2] = 0$$

If $l_1 = l_2 = l$, then

$$M_1(t)[\coth kl - \cot kl] = 0$$

which means that such a beam has two types of vibrations.

1. The first type of vibration occurs if $M_1(t) = 0$.

In this case, the behavior of each span is similar to the behavior of a one-span simply-supported beam.

2. The second type of vibration occurs if

$$\coth kl - \cot kl = 0$$

In this case, the behavior of each span is similar to the behavior of a one-span pinned-clamped beam.

For both types of vibrations, the frequency equation, mode shape and nodal points are presented in Tables 3.9, 5.3 and 5.4 respectively.

Example. A non-uniform beam with different lengths of spans, mass and rigidity is shown in Fig. 5.7. Find the relationship m_2/m_1 which leads to the fundamental frequency parameter

$$\lambda_1 = 2.6, \quad \omega_1 = \frac{\lambda_1^2}{l_1^2} \sqrt{\frac{EI_1}{m_1}}.$$

Solution. For support 1, the Three-Moment Equation in terms of Zal'tsberg functions is

$$\frac{\psi_1}{i_1} M_0 + \left(\frac{\varphi_1}{i_1} + \frac{\varphi_2}{i_2} \right) M_1 + \frac{\psi_2}{i_2} M_2 = 0, \quad i_1 = \frac{EI_1}{l_1} = i, \quad i_2 = \frac{EI_2}{l_2} = i$$

Since support moments $M_0 = M_2 = 0$, then the frequency equation may be rewritten in the form

$$\varphi_1 + \varphi_2 = 0$$

or

$$\coth \lambda_1 - \cot \lambda_1 + \coth \lambda_2 - \cot \lambda_2 = 0$$

Since $\lambda_2 = n\lambda_1$, then the frequency equation becomes

$$\coth \lambda_1 - \cot \lambda_1 + \coth n\lambda_1 - \cot n\lambda_1 = 0$$

Using Table 5.2, the frequency equation leads to

$$2.67334 + \coth n\lambda_1 - \cot n\lambda_1 = 0$$

The root of the above equation is

$$\lambda_2 = n\lambda_1 = 2.6n = 3.40968 \rightarrow n = 1.3114$$

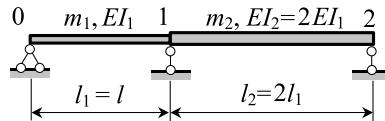

FIGURE 5.7. Design diagram of a non-uniform beam.

Thus, the required relationship is

$$\frac{m_2}{m_1} = \frac{n^4}{\left(\frac{l_2}{l_1}\right)^4} \frac{1}{EI_1/EI_2} = 0.3697$$

Frames. For dynamical calculation of frames with n lumped masses m_i (distributed masses are neglected), represent the displacement of each mass m_i in general canonical form

$$y_i = \delta_{i1}X_1 + \delta_{i2}X_2 + \cdots + \delta_{ir}X_r + \cdots + \delta_{in}X_n + \Delta_{ip} \quad (5.8)$$

where $X_1, X_2, \dots, X_r, \dots, X_n$ = inertial forces of the corresponding masses;

δ_{ik} = unit displacements (Chapter 2.3);

Δ_{ip} = displacement in the direction of X_i caused by external vibrational loads. For the eigenvalue and eigenfunction problems, the free terms of canonical form $\Delta_{ip} = 0$.

In the case of harmonic free vibrations, displacement of mass m_i , its acceleration and inertial force are

$$y_i = a_i \sin \omega t; \quad \ddot{y}_i = -a_i \omega^2 \sin \omega t, \quad X_i = -m_i \ddot{y}_i$$

Substituting the above expressions into Equation (5.8) yields

$$\begin{aligned} \delta_{11}^*X_1 + \delta_{12}X_2 + \cdots + \delta_{1n}X_n &= 0 \\ \delta_{21}X_1 + \delta_{22}^*X_2 + \cdots + \delta_{2n}X_n &= 0 \\ \cdots &\cdots \\ \delta_{n1}X_1 + \delta_{n2}X_2 + \cdots + \delta_{nn}^*X_n &= 0 \end{aligned} \quad (5.9)$$

where

$$\delta_{ii}^* = \delta_{ii} - \frac{1}{m_i \omega^2}$$

The non-trivial solution of Equations (5.9) with respect to a_i yields the following frequency (secular) equation

$$\begin{vmatrix} \delta_{11}m_1 - 1/\omega^2 & \delta_{12}m_2 & \cdots & \delta_{1n}m_n \\ \delta_{21}m_1 & \delta_{22}m_2 - 1/\omega^2 & \cdots & \delta_{2n}m_n \\ \cdots & \cdots & \cdots & \cdots \\ \delta_{n1}m_1 & \delta_{n2}m_2 & \cdots & \delta_{nn}m_n - 1/\omega^2 \end{vmatrix} = 0 \quad (5.10)$$

The unit displacements may be calculated according to Equations (2.2)–(2.4). Equation (5.10) is very convenient for the solution of eigenvalue problems in the case of statically determinate systems. If a system is statically indeterminate, then calculation of unit displacements presents difficulties. In this case, the slope-deflection method is an efficient one.

Equations (5.9) and the canonical equations of the Force Method for statical problems are similar. However, there is a fundamental difference. The unknown X_i of system (5.9) are not the reactions of the discarded constraints of a statically indeterminate system, but amplitudes of inertial forces, which can be produced both in statically determinate and indeterminate systems.

5.1.3 Slope-Deflection Method

This method may be effectively applied for dynamic calculation of framed statically indetermined systems with or without distributed and lumped masses.

In order to obtain a conjugate redundant system (basic, or primary system), the additional introduced constraints must prevent rotation of all rigid joints as well as all independent displacements of these joints. Canonical equations of the slope-deflection method are:

$$\begin{aligned} r_{11}Z_1 + r_{12}Z_2 + \cdots + r_{1n}Z_n + R_{1n} &= 0 \\ r_{21}Z_1 + r_{22}Z_2 + \cdots + r_{2n}Z_n + R_{2p} &= 0 \\ \dots & \\ r_{n1}Z_1 + r_{n2}Z_2 + \cdots + r_{nn}Z_n + R_{np} &= 0 \end{aligned} \quad (5.11)$$

The equations of the slope-deflection method negate the existence of reactive moments and forces developed by imaginary constraints in conjugate systems.

The system of equation (5.11) contains amplitudes of vibrational displacements Z_i for unknown variables. Coefficients r_{ik} with unknown Z_i variables represent amplitude values of reactions of introduced constraints i due to unit vibrational displacements of restriction k . The free terms, R_{ip} , are amplitudes of reactions of constraints due to vibrational load; in the case of the free vibrations these free terms are zeros.

The amplitudes of vibrational displacements Z_i take into account inertial forces of concentrated and/or distributed masses of elements of a system, by means of correction functions to the formulas representing static reactions.

The effects of inertial forces of distributed and/or lumped masses are taken into account by correction functions, whose numerical values depend on a frequency parameter. The simplest case for dynamical reactions of massless elements with one lumped mass is presented in Table 4.3. Smirnov's functions take into account the exact effects of inertial forces of uniformly distributed masses. Their analytical expressions in different forms are presented in Tables 4.4 and 4.5, and numerical values are presented in Table 4.6. Bolotin's functions take into account the approximate effects of inertial forces of uniformly distributed masses, and their analytical expressions are presented in Table 4.7. Kiselev's functions take into account the exact effects of inertial forces of uniformly distributed masses and one concentrated mass, and their analytical expressions are presented in Table 4.8.

In order to determine eigenvalues of the framed system, the determinant of coefficients with unknown variables has to equal zero

$$\begin{vmatrix} r_{11} & r_{12} & \dots & r_{1n} \\ r_{21} & r_{22} & \dots & r_{2n} \\ \dots & \dots & \dots & \dots \\ r_{n1} & r_{n2} & \dots & r_{nn} \end{vmatrix} = 0 \quad (5.12)$$

5.2 ONE-SPAN BEAMS

Frequency equations, eigenvalues, nodal points and asymptotical formulas for eigenvalues for classical and special boundary conditions are presented in Tables 5.3 and 5.4. The

corresponding eigenfunctions in forms 1 and 2 are presented in Table 5.5. These forms are as follows.

$$\text{Form 1. } X_n(x) = \cosh \frac{\lambda_n x}{l} \pm \cos \frac{\lambda_n x}{l} - \sigma_n \left(\sinh \frac{\lambda_n x}{l} \pm \sin \frac{\lambda_n x}{l} \right) \quad (5.13)$$

$$\text{Form 2. } X_n(x) = \sin \frac{\lambda_n x}{l} + A_n \cos \frac{\lambda_n x}{l} + B_n \sinh \frac{\lambda_n x}{l} + C_n \cosh \frac{\lambda_n x}{l} \quad (5.14)$$

The ordinates of mode shape vibration for one-span and multispan beams with classical boundary conditions are presented in Appendices A and B respectively.

5.2.1 Eigenvalues

1. Eigenvalues for beams with **Classical Boundary Conditions** are discussed in (Rogers, 1959; Babakov, 1965; Blevins, 1979; Pilkey, 1994; Inman, 1996; Young, 1982).
2. Eigenvalues for beams with **Special Boundary Conditions** are discussed in (Bezukhov *et al.*, 1969; Pilkey, 1994; Geradin and Rixen, 1997).

5.2.2 Eigenfunctions

Eigenfunctions for beams with guided support (Pilkey, 1994)

$$\text{Guided-pinned beam: } X(x) = \cos \frac{(2n-1)\pi x}{2l}$$

$$\text{Guided-guided beam: } X(x) = \cos \frac{n\pi x}{l}$$

$$\text{Free-guided beam: } X(x) = \cosh k_n x + \cos k_n x - \sigma_n (\sinh k_n x + \sin k_n x)$$

where

$$\sigma_n = \frac{\sinh k_n l - \sin k_n l}{\cosh k_n l + \cos k_n l}$$

5.3 ONE-SPAN BEAM WITH OVERHANG

5.3.1 Pinned-pinned one-span beam with overhang (Fig. 5.8)

Frequency equation (Morrow, 1908)

$$(\cosh kl \sin kl - \sinh kl \cos kl)(\cosh kc \sin kc - \sinh kc \cos kc) \\ - 2 \sinh kl \sin kl(1 + \cosh kc \cos kc) = 0$$

The least root, $\lambda = kl$, of the frequency equation according to parameter c/l is presented in Table 5.6 (Pfeiffer, 1928; Filippov, 1970)

$$\text{Frequency of vibration } \omega = k^2 \sqrt{\frac{EI}{m}} = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$$

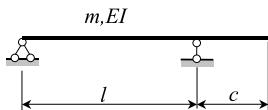

FIGURE 5.8. Pinned-pinned beam with one overhang.

TABLE 5.6. Pinned-pinned beam with overhang: the least root of a frequency equation

c/l	∞	1	$3/4$	$1/2$	$1/3$	$1/4$	$1/5$	$1/6$	$1/7$	$1/8$	$1/9$	$1/10$	0
kl	1.8751	1.5059	1.9017	2.5189	2.9404	3.0588	3.0997	3.1175	3.1264	3.1314	3.1344	3.1364	π

Special cases

- Case $c/l = 0$ corresponds a pinned-pinned beam without an overhang. The frequency equation is $\sin kl = 0$. Eigenvalues and nodal points for different mode shapes are presented in Table 5.3.

2. Case $c/l = \infty$ corresponds to a clamped-free beam with length c . The frequency equation is $1 + \cosh kc \cos kc = 0$. Eigenvalues and nodal points of the mode shape are presented in Table 5.3.

If c/l is small, then the approximate solution of the frequency equation is (Chree, 1914)

$$kl = \pi \left(1 - \frac{\pi^2}{6} \frac{c^3}{l^3} \right)$$

If $c/l < 0.5$, then the error according to the Chree approximation is less than 1%.

Example. Calculate the frequency of vibration for a pinned-pinned beam with one overhang, if $l = 8\text{m}$, $c = 2\text{m}$ (Fig. 5.8).

Solution. Since the parameter $c/l = 0.25$, then $\lambda = kl = 3.0588$ (Table 5.1). The frequency of vibration is:

$$\omega = k^2 \sqrt{\frac{EI}{m}} = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}} = \frac{3.0588^2}{8^2} \sqrt{\frac{EI}{m}}$$

The Chree formulae gives the following eigenvalue

$$kl = \pi \left(1 - \frac{1}{6} \pi^2 \frac{c^3}{l^3} \right) = \pi \left(1 - \frac{1}{6} \pi^2 \frac{2^3}{8^3} \right) = 3.0608$$

5.3.2 Beam with two equal overhangs

Design diagram and notation are presented in Fig. 5.9(a). Frequency of vibration is

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}, \quad l = l_1 + \frac{l_2}{2}$$

Symmetric vibration. The frequency equation may be written in the following form (Anan'ev, 1946)

$$C[\lambda(1 - l^*)]E(\lambda l^*) - B(\lambda l^*)A[\lambda(1 - l^*)] = 0$$

where $l^* = l_1/l$ is a dimensionless parameter, and A , B , C and E are Hohenemser-Prager's functions.

The fundamental frequency corresponds to symmetrical shape vibration. The fundamental frequency parameter λ in terms of l^* is presented in Fig. 5.9(b).

Antisymmetric vibration. The frequency equation may be presented in the following form

$$S_1[\lambda(1 - l^*)]E(\lambda l^*) - B[\lambda(1 - l^*)]B(\lambda l^*) = 0 \quad (5.15)$$

Example. Calculate the fundamental frequency of vibration for a beam with two equal overhangs. if $l_1 = 1\text{m}$, $l_2 = 8\text{m}$ (Fig. 5.9(a)).

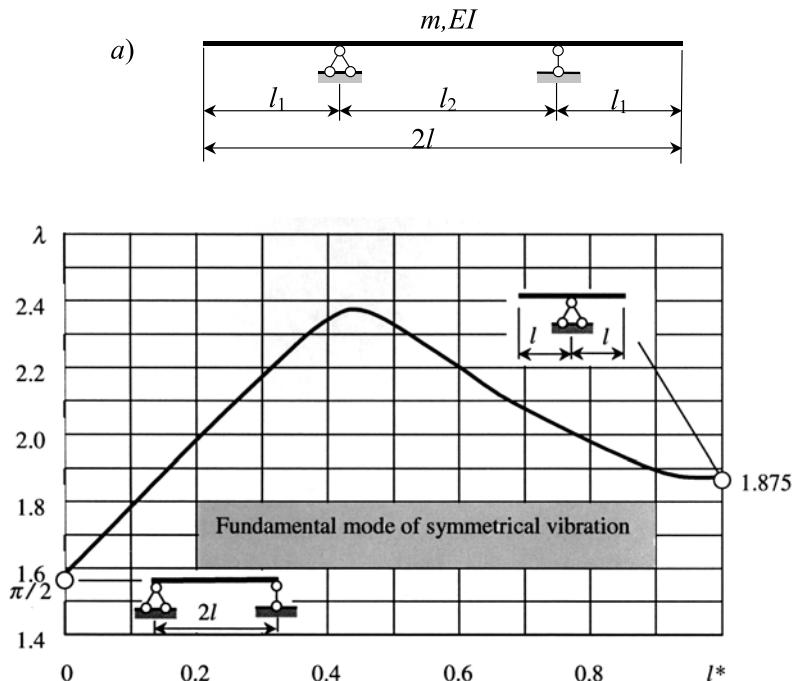

FIGURE 5.9. Beam with two equal overhangs. (a) Design diagram and notation; (b) frequency parameter λ for symmetric vibration.

Solution. The half-length of the beam $l = l_1 + 0.5l_2 = 5m$, so a non-dimensional parameter $l^* = l_1/l = 0.2$.

The frequency equation (5.14) leads to

$$C(0.8\lambda)E(0.2\lambda) - B(0.2\lambda)A(0.8\lambda) = 0$$

The least root is $\lambda = 1.95$.

The frequency of vibration is

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}} = \frac{1.95^2}{5^2} \sqrt{\frac{EI}{m}}$$

5.3.3 Clamped-pinned beam with overhang

The design diagram and notation are presented in Fig. 5.10.

Frequency of vibration

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$$

The frequency equation may be presented in the following form

$$\frac{S[\lambda(1-l^*)]}{T[\lambda(1-l^*)]} \{S(\lambda)V(\lambda l^*) - T(\lambda)U(\lambda l^*)\} + \{S(\lambda)U(\lambda l^*) - V(\lambda)V(\lambda l^*)\} = 0 \quad (5.16)$$

where $l^* = l_1/l$, and S , T , U and V are Krylov-Duncan functions.

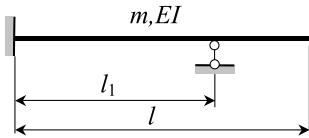

FIGURE 5.10. Design diagram of a clamped-pinned beam with overhang.

Special case. Case $l_1/l = 1$ corresponds to clamped-pinned beam without an overhang. In this case $l^* = 1$, $S(0) = 1$, $T(0) = 0$ and the frequency equation (5.16) becomes

$$S(\lambda)V(\lambda) - T(\lambda)U(\lambda) = 0$$

which leads to

$$\cosh \lambda \sin \lambda - \sinh \lambda \cos \lambda = 0$$

Eigenvalues and nodal points for different mode shapes of vibration are presented in Tables 5.3 and 5.5.

5.4 FUNDAMENTAL INTEGRALS

Fundamental integrals are the additional characteristics of a system, which are used for dynamic analysis of free vibration using approximate methods (see Chapter 2) as well as for dynamic analysis of forced vibrations.

5.4.1 Integrals $\int_0^l X_k^2 dx$ for beams with classical boundary conditions

The solution of the differential equation of transverse vibration (5.1) can be presented in the following form

$$y(\xi, t) = \sum X_k(\xi)(B_k \cos \omega t + C_k \sin \omega t) \quad (5.17)$$

The differential equation of mode shape is

$$X'''' - b^2 X = 0, \quad b^2 = \lambda^4, \quad \omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}} \quad (5.18)$$

Constants B and C can be found from the initial conditions

$$\text{at } t = 0; \quad y(\xi, 0) = f(\xi), \quad \frac{\partial y(\xi, 0)}{\partial t} = f_1(\xi), \quad \xi = \frac{x}{l}$$

The constants B_k and C_k take into account not only initial conditions, but boundary conditions as well.

Constants B_k and C_k are determined as follows

$$B_k = \frac{\int_0^l f(\xi) d\xi}{\int_0^l X_k^2(\xi) d\xi}; \quad C_k = \frac{\int_0^l f_1(\xi) d\xi}{\omega \int_0^l X_k^2(\xi) d\xi}; \quad (5.19)$$

Integrals $\int_0^l X_k^2 dx$ depend only on types of supports. For beams with classical boundary conditions, these integrals are presented in Table 5.7 in terms of X and their derivatives at $x = 0$ (Form 1) and $x = l$ (Form 2).

TABLE 5.7. Beams with classical boundary condition: different presentations of fundamental integral $\frac{4}{l} \int_0^l X_k^2 dx$

Boundary Condition		Integral $\frac{4}{l} \int_0^l X^2 dx$	
$x = 0$	$x = l$	Form 1	Form 2
Clamped	Clamped	$[X''(0)]^2$	
Simple supported	Clamped	$-2X'(0)X'''(0)$	$[X''(l)]^2$
Free	Clamped	$X^2(0)$	
Clamped	Simple supported	$[X''(0)]^2$	
Simple supported	Simple supported	$2[X'(0)]^2$	$-2X'(l)X'''(l)$
Free	Simple supported	$X^2(0)$	
Clamped	Free	$[X''(0)]^2$	
Simple supported	Free	$-2X'(0)X'''(0)$	$X^2(l)$
Free	Free	$X^2(0)$	

Note: X' derivatives with respect to the argument of eigenfunction X , but not with respect to x .

Example. Calculate the integral $\int_0^l X^2(x) dx$ for a pinned-pinned beam.

Solution. For a simply supported beam eigenfunction, its derivatives with respect to the argument are

$$X_k = \sin \frac{k\pi x}{l}, \quad X'_k(x) \cos \frac{k\pi x}{l}$$

$$X''_k(x) = -\sin \frac{k\pi x}{l}, \quad X'''_k(x) = -\cos \frac{k\pi x}{l}$$

Integral $\int_0^l X^2 dx$ may be calculated by using Table 5.5.

Form 1 (using the boundary condition at the left-hand end)

$$\int_0^l \sin^2 \frac{k\pi x}{l} dx = \frac{l}{2} [X'(0)]^2 = \frac{l}{2} \left(\cos \frac{k\pi 0}{l} \right)^2 = \frac{l}{2}$$

Form 2 (using the boundary condition at the right-hand end)

$$\int_0^l \sin^2 \frac{k\pi x}{l} dx = -\frac{l}{2} X'(l) X'''(l) = -\frac{l}{2} \cos \frac{k\pi l}{l} \left(-\cos \frac{k\pi l}{l} \right) = \frac{l}{2}$$

Numerical values of integrals $\int_0^l X^2(x) dx$ and related ones for beams with different boundary conditions are presented in Table 5.8. Some useful integrals concerning the eigenvalue problem are presented in Appendix C.

5.4.2 Integrals with one index

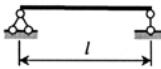

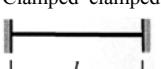

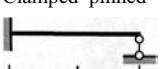

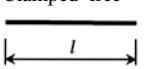

Numerical values of several fundamental integrals for beams with different boundary conditions and numbers of mode vibration are presented in Tables 5.8 and 5.9 (Babakov, 1965).

The following integrals may be presented in analytical form in terms of eigenfunctions and their derivatives (Weaver *et al.* 1990)

$$(a) \int_0^l X_k^2 dx = \frac{l}{4} [X_k^2 - 2X'_k X'''_k + (X''_k)^2]_{x=l} \quad (5.20)$$

$$(b) \int_0^l X_k^{IV} X_k dx = \int_0^l (X''_k)^2 dx \quad (5.21)$$

5.4.3 Integrals with two indexes

Integrals with two indexes occur in the approximate calculation of frequencies of vibration of deformable systems. These integrals satisfy the following relationship

$$\int_0^l X_i' X_j' dx = - \int_0^l X_i X_j'' dx \quad (5.22)$$

where i and j are the number of modes of vibration. Numerical values of these integrals are presented in Table 5.9 (Babakov, 1965).

TABLE 5.9. Beams with classical boundary condition: numerical values for some fundamental integrals with two indexes

5.5 LOVE AND BERNOULLI-EULER BEAMS, FREQUENCY EQUATIONS AND NUMERICAL RESULTS

Love equations take into account individual contributions of shear deformation and rotary inertia but omit their joint contribution (Table 3.1).

Complete Love equations may be presented as the following system of equations

$$\begin{aligned} EI \frac{\partial^4 y}{\partial x^4} + \frac{\gamma A}{g} \frac{\partial^2 y}{\partial t^2} - \left(\frac{\gamma I}{g} + \frac{EI}{gk} \frac{\gamma}{G} \right) \frac{\partial^4 y}{\partial x^2 \partial t^2} &= 0 \\ EI \frac{\partial^4 \psi}{\partial x^4} + \frac{\gamma A}{g} \frac{\partial^2 \psi}{\partial t^2} - \left(\frac{\gamma I}{g} + \frac{EI}{gk} \frac{\gamma}{G} \right) \frac{\partial^4 \psi}{\partial x^2 \partial t^2} &= 0 \end{aligned} \quad (5.23)$$

where y = transverse displacement;

ψ = angle of rotation of the cross-section;

k = shear coefficient;

E = Young's modulus;

G = modulus of rigidity.

Shear coefficient k for various types of cross-section are presented in Table 11.1.

Truncated Love equations are obtained from Equations (5.23) and are presented as the following system of equations:

$$\begin{aligned} EI \frac{\partial^4 y}{\partial x^4} + \frac{\gamma A}{g} \frac{\partial^2 y}{\partial t^2} - \frac{EI}{gk} \frac{\gamma}{G} \frac{\partial^4 y}{\partial x^2 \partial t^2} &= 0 \\ EI \frac{\partial^4 \psi}{\partial x^4} + \frac{\gamma A}{g} \frac{\partial^2 \psi}{\partial t^2} - \frac{EI}{gk} \frac{\gamma}{G} \frac{\partial^4 \psi}{\partial x^2 \partial t^2} &= 0 \end{aligned} \quad (5.24)$$

The special case of system (5.24), when shear deformation and rotary inertia are not considered is given by Bernoulli-Euler theory (Chapter 1)

$$EI \frac{\partial^4 y}{\partial x^4} + \frac{\gamma A}{g} \frac{\partial^2 y}{\partial t^2} = 0 \quad (5.25)$$

The general solution of the Love system of equations (5.23)

$$\begin{aligned} y &= X e^{j\omega t} \\ \psi &= \Psi e^{j\omega t} \end{aligned} \quad (5.26)$$

Normalized equations for total transverse vibration mode and rotational vibrational mode are

$$\begin{aligned} X'''' + \lambda^4 (r^2 + s^2) X'' - \lambda^4 X &= 0 \\ \Psi'''' + \lambda^4 (r^2 + s^2) \Psi'' - \lambda^4 \Psi &= 0 \end{aligned} \quad (5.27)$$

where

$$\lambda^4 = \frac{m\omega^2 l^4}{EI}, \quad m = \rho A$$

$$r^2 = \frac{I}{Al^2}$$

$$s^2 = \frac{EI}{kAGl^2} = r^2 \frac{E}{kG}$$

The prime denotes differentiation with respect to $\xi = \frac{x}{l}$.

TABLE 5.10. Uniform Love and Bernoulli-Euler beams. Frequency equations (Abramovich and Elishakoff, 1990)

Type of beam	Boundary conditions	Frequency equation (Love theory, $\lambda^4 r^2 s^2 < < 1$)	Frequency equation (Bernoulli-Euler theory)	Roots of frequency equation (Love theory)	Roots of frequency equation (Bernoulli-Euler theory)	Fig. 5.11

TABLE 5.10. (continued)

Type of beam	Boundary conditions	Frequency equation (Love theory, $\lambda^4 r^2 s^2 < < 1$)	Frequency equation (Bernoulli-Euler theory)	Roots of frequency equation (Love theory)
Pinned-guided	$X(0) = \psi'(0) = 0$ $\psi'(1) = \frac{1}{l} X'(1) - \psi(1)$	$\cos(\lambda^2 s_2) = 0$	$\cos \lambda = 0$	$\lambda^2 = \frac{(2n-1)^2 n^2}{4 \cdot \sqrt{1 + \left(\frac{2n-1}{2} n\right)^2 (s^2 + r^2)}}$
Guided-guided	$\psi(1) = \frac{1}{l} X'(0) - \psi(0) = 0$ $\psi(1) = \frac{1}{l} X'(1) - \psi(1) = 0$	$\sin(\lambda^2 s_2) = 0$	$\sin \lambda = 0$	$\lambda^2 = \frac{(n\pi)^2}{\sqrt{1 + (n\pi)^2 (s^2 + r^2)}}$
Free-free	$\psi'(0) = \frac{1}{l} X'(0) - \psi(0) = 0$ $\psi'(1) = \frac{1}{l} X'(1) - \psi(1) = 0$	$2 - 2 \cosh(\lambda^2 s_1) \cos(\lambda^2 s_2)$ $+ \frac{\lambda^2 [(3r^2 - s^2) + \lambda^4 r^4 (s^2 + r^2)]}{1 + \lambda^4 s^2 r^2}$ $\times \sinh(\lambda^2 s_1) \sin(\lambda^2 s_2) = 0$	$\cos \lambda \cosh \lambda = 1$	Fig. 5.11
Free-pinned	$\psi'(0) = \frac{1}{l} X'(0) - \psi(0) = 0$ $X(1) = \psi'(1) = 0$	$\zeta \tan(\lambda^2 s_2) - \frac{s_1}{s_2} \tanh(\lambda^2 s_1) = 0$	$\tanh \lambda - \tan \lambda = 0$	Fig. 5.11
Free-guided	$\psi'(0) = \frac{1}{l} X'(0) - \psi(0) = 0$ $\psi(1) = \frac{1}{l} X'(1) - \psi(1) = 0$	$\frac{s_1}{s_2} \tan(\lambda^2 s_2) + \zeta \tanh(\lambda^2 s_1) = 0$	$\tanh \lambda + \tan \lambda = 0$	Fig. 5.11

The normal modes X and Ψ are general solutions of Equations (5.27), which may be presented as the following expressions

$$X(\xi) = B_1 \cosh(\lambda^2 s_1 \xi) + B_2 \sinh(\lambda^2 s_1 \xi) + B_3 \cos(\lambda^2 s_2 \xi) + B_4 \sin(\lambda^2 s_2 \xi)$$

$$\Psi(\xi) = C_1 \cosh(\lambda^2 s_1 \xi) + C_2 \sinh(\lambda^2 s_1 \xi) + C_3 \cos(\lambda^2 s_2 \xi) + C_4 \sin(\lambda^2 s_2 \xi)$$

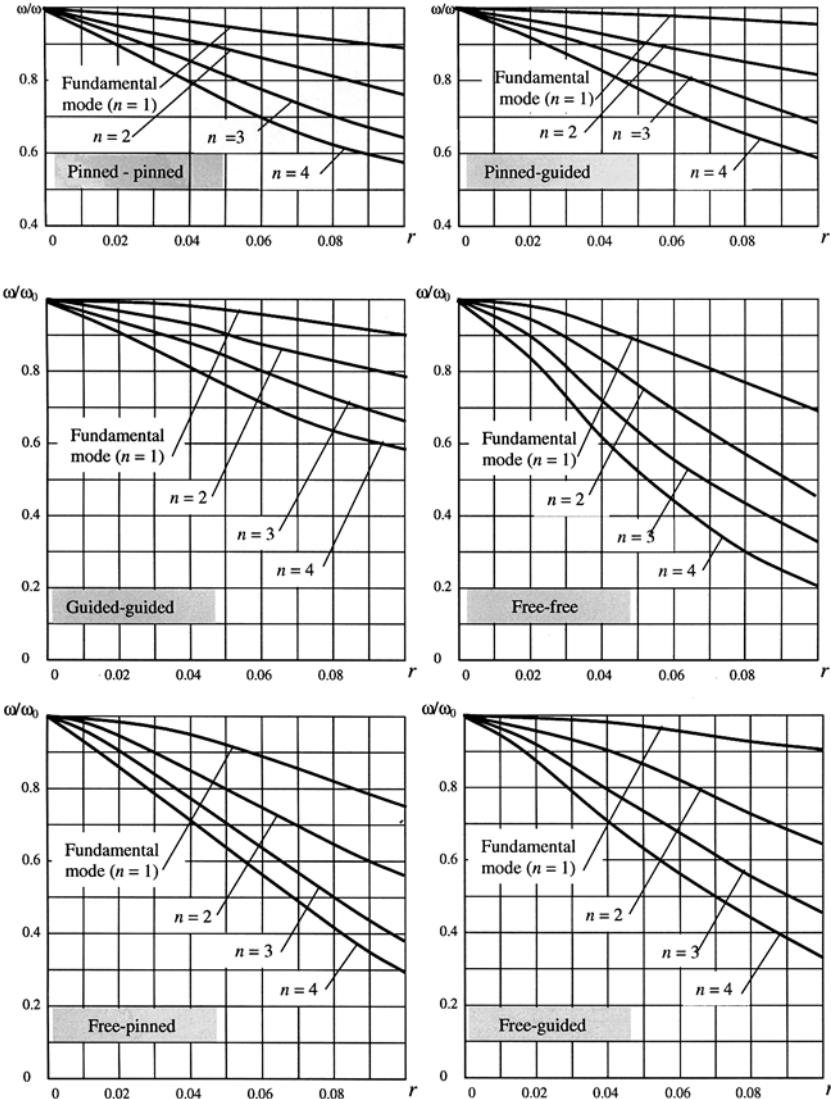

FIGURE 5.11. Frequency ratios ω/ω_0 versus parameter $r = I/AI^2$ for the first four modes of vibration n .

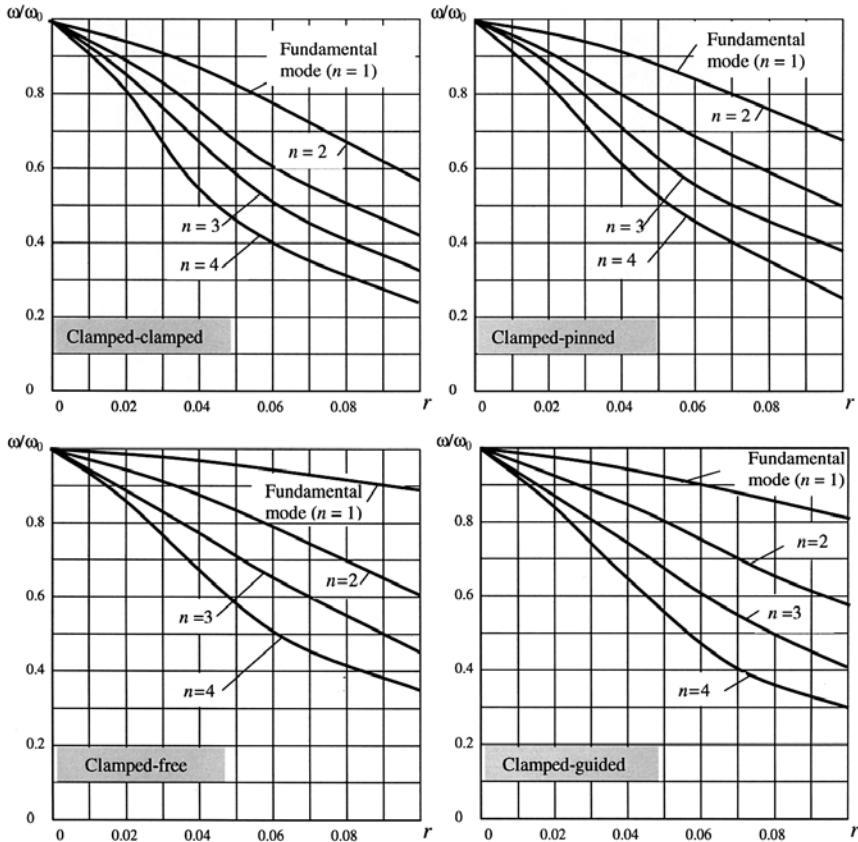

FIGURE 5.11. (Continued)

where

$$\begin{pmatrix} s_1 \\ s_2 \end{pmatrix} = \frac{1}{\sqrt{2}} \sqrt{\mp(r^2 + s^2) + \sqrt{(r^2 + s^2)^2 + \frac{4}{\lambda^4}}}$$

Frequency equations for uniform Love and Bernoulli-Euler beams with different boundary conditions are presented in Table 5.8. In this table, the parameter

$$\zeta = \frac{s_2^2 - s^2}{s_1^2 + s^2}$$

Numerical results. If parameters r and b for a given beam are known, the frequencies of vibration can be calculated from the appropriate frequency equation (Table 5.10). The solution in closed form may be found only for the simplest cases.

Frequency ratios ω/ω_0 for one-span beams under different boundary conditions in terms of $r = I/AL^2$ and different modes of vibration ($n = 1, 2, 3, 4$) are presented in Fig. 5.11, where ω is frequency of vibration based on the Love equation; ω_0 is frequency of vibration based on Bernoulli-Euler equation (Abramovich, Elishakoff, 1990).

These are graphs constructed for

$$E/G = 8/3, \quad k = 2/3, \quad s = 2r$$

CHAPTER 6

BERNOULLI-EULER UNIFORM ONE-SPAN BEAMS WITH ELASTIC SUPPORTS

This chapter is devoted to Bernoulli–Euler uniform one-span beams with elastic (translational and torsional) supports. Fundamental characteristics, such as frequency equations, eigenvalues and eigenfunctions, are presented. For many cases, the frequency equation is presented in the different forms that occur in the various scientific examples. Special cases are discussed.

NOTATION

A	Cross-sectional area
A, B, C, E, S_1	Hohenemser–Prager functions
E	Young's modulus
EI	Bending stiffness
I_z	Moment inertia of a cross-section
k_n	Frequency parameter, $k_n = \sqrt[4]{\frac{m\omega^2}{EI}}$, $\lambda = kl$
k_{tr}	Translational stiffness coefficients
k_{rot}	Rotational stiffness coefficients
k_{tr}^*	Dimensionless translational stiffness coefficients, $k_{tr}^* = \frac{k_{tr}l^3}{EI}$
k_{rot}^*	Dimensionless rotational stiffness coefficients, $k_{rot}^* = \frac{k_{rot}l}{EI}$
l	Length of the beam
m	Mass per unit length, $m = \rho A$
S, T, U, V	Krylov–Duncan functions
x	Spatial coordinate
x, y, z	Cartesian coordinates

$X(x)$	Mode shape
α, γ	Dimensionless auxiliary parameters
λ	Frequency parameter, $\lambda^4 EI = ml^4 \omega^2$
ξ	Dimensionless coordinate, $\xi = \frac{x}{l}$, $0 \leq \xi \leq 1$
ρ	Density of material
ω	Natural frequency, $\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$

6.1 BEAMS WITH ELASTIC SUPPORTS AT BOTH ENDS

Exact frequency equations and expressions for mode shape vibration for uniform beams with uniformly distributed masses and elastic supports at both ends are presented in Table 6.1. (Anan'ev, 1946; Gorman, 1975). These equations may be also presented in terms of Krylov–Duncan and Hohenemser–Prager functions. Frequency equations for special cases are presented in Table 6.2.

6.1.1 Numerical results

Beam with two translational springs supports

Stiffnesses are equal (Fig. 6.1). In this case it is convenient to calculate a half-beam. Design diagrams for symmetrical and antisymmetrical vibration and corresponding frequency equations in terms of (1) Krylov–Duncan functions, (2) Hohenemser–Prager functions, and (3) in explicit form are presented in Table 6.3.

The frequency vibration is $\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$, where λ is a root of a frequency equation. The roots of the frequency equation in terms of $k^* = kl^3/EI$ for symmetrical vibration are presented in Fig. 6.2. Design diagrams at the left and right of the graph present limiting cases; corresponding frequency parameters are shown by a circle.

The roots of frequency equation in terms of $k^* = kl^3/EI$ for antisymmetric vibration are presented in Fig. 6.3.

Stiffnesses are different (Fig. 6.4). Frequency equation (case 1, Table 6.4) may be rewritten as follows

$$k_2^* = \lambda^3 \frac{(1+n)B(\lambda) \pm \sqrt{(1+n)^2 B^2(\lambda) + 4nD(\lambda)S_1(\lambda)}}{2nS_1(\lambda)} \quad (6.1)$$

where $B(\lambda), D(\lambda), S_1(\lambda)$ are Hohenemser–Prager functions; and the dimensionless parameters are

$$n = \frac{k_1^*}{k_2^*} = \frac{k_1}{k_2}, \quad k_1^* = \frac{k_1 l^3}{EI}, \quad k_2^* = \frac{k_2 l^3}{EI}$$

The natural frequency of vibration is $\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$, where λ is a root of frequency equation (6.1). Frequency parameters λ in terms of k_2^* and parameter n are presented in Fig. 6.5.

TABLE 6.1. Frequency equation and mode shape vibration for one-span beams with elastic supports at both ends

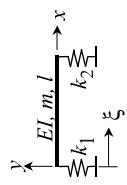

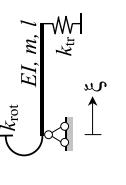

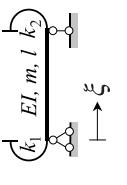

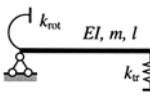

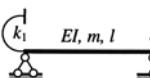

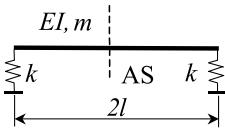

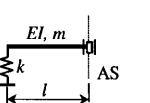

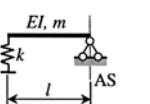

Beam Type	Frequency equation and mode shape $X(\xi)$	Parameters
	$(k_1^*)^2 + k_{\text{rot}}^* \frac{\lambda^3(1+\alpha)(\sinh \lambda \cos \lambda - \cosh \lambda \sin \lambda) - \lambda^6(1 - \cos \lambda \cosh \lambda)}{2x \sinh \lambda \sinh \lambda} + \frac{2\lambda \sinh \lambda \sinh \lambda}{2x \sinh \lambda \sinh \lambda} = 0$ $X(\xi) = \sin \lambda \xi + \frac{\sinh \lambda}{\sinh \lambda} \sinh \lambda \xi + \gamma (\cos \lambda \xi + \cosh \lambda \xi + \gamma_1 \sinh \lambda \xi)$	$\gamma = \frac{\sinh \lambda - \sin \lambda}{2 \frac{\lambda^3}{\lambda^3} \sinh \lambda + \cos \lambda - \cosh \lambda}, \alpha = \frac{k_2^*}{k_1^*}$ $\gamma_1 = \frac{\cos \lambda - \cosh \lambda}{\sinh \lambda}$
	$(k_{\text{rot}})^2 + k_{\text{rot}}^* \frac{-\lambda^3(1 + \cos \lambda \cosh \lambda) - 2\lambda \sinh \lambda \sinh \lambda}{\cos \lambda \sinh \lambda - \sin \lambda \cosh \lambda} - \frac{\lambda^4}{\alpha} = 0$ $X(\xi) = \sin \lambda \xi + \frac{\sinh \lambda}{\sinh \lambda} \sinh \lambda \xi + \gamma (\cos \lambda \xi - \cosh \lambda \xi + \gamma_1 \sinh \lambda \xi)$	$\gamma = \frac{-\left(1 + \frac{\sin \lambda}{\sinh \lambda}\right)}{\frac{2\lambda}{k_{\text{rot}}} + \cos \lambda + \frac{\cosh \lambda}{\sinh \lambda}}, \alpha = \frac{k_{\text{tr}}^*}{k_{\text{rot}}^*}$ $\gamma_1 = \frac{\cos \lambda + \cosh \lambda}{\sinh \lambda}$
	$(k_1^*)^2 + k_{\text{rot}}^* \frac{\alpha(1 - \cos \lambda \cosh \lambda) - \cos \lambda \sinh \lambda}{\cos \lambda - \cosh \lambda - 2 \frac{\lambda}{k_1^*} \sinh \lambda} + \frac{2\lambda^2 \sinh \lambda \sinh \lambda}{\cos \lambda - \cosh \lambda - 2 \frac{\lambda}{k_1^*} \sinh \lambda} = 0$ $X(\xi) = \sin \lambda \xi - \sinh \lambda \xi + \gamma \left(\cos \lambda \xi - \cosh \lambda \xi - \frac{2\lambda}{k_1^*} \sinh \lambda \xi \right)$	$\gamma = \frac{\sinh \lambda - \sin \lambda}{\cos \lambda - \cosh \lambda - 2 \frac{\lambda}{k_1^*} \sinh \lambda}, \alpha = \frac{k_2^*}{k_1^*}$

*Eigenfunctions, nodal points and several types of fundamental integrals for one-span uniform beams with classical boundary conditions are presented in Chapter 5.

**FIGURE 6.1.** Beam with two translational springs supports, AS is axis of symmetry.**TABLE 6.3.** Symmetrical beams with elastic supports: frequency equation for symmetrical and antisymmetrical vibrations

Type of vibration and design diagram	Frequency equation in different forms	Special cases and corresponding frequency equation
Symmetrical	$1. \frac{kl^3}{EI} = \lambda^3 \frac{S(\lambda)T(\lambda) - U(\lambda)V(\lambda)}{S^2(\lambda) - U^2(\lambda)}$ $2. \frac{kl^3}{EI} = \lambda^3 \frac{A(\lambda)}{C(\lambda)}$ $3. \frac{kl^3}{EI} = \lambda^3 \frac{\cosh \lambda \sin \lambda + \sinh \lambda \cos \lambda}{2 \cosh \lambda \cos \lambda}$	$k = 0$ (free-sliding half-beam) $A(\lambda) = 0$ or $\tan \lambda + \tanh \lambda = 0$ (Table 5.4)
		
Antisymmetrical	$1. \frac{kl^3}{EI} = \lambda^3 \frac{T(\lambda)U(\lambda) - S(\lambda)V(\lambda)}{T^2(\lambda) - V^2(\lambda)}$ $2. \frac{kl^3}{EI} = \lambda^3 \frac{B(\lambda)}{S_1(\lambda)}$ $3. \frac{kl^3}{EI} = \lambda^3 \frac{\cosh \lambda \sin \lambda - \sinh \lambda \cos \lambda}{2 \sinh \lambda \sin \lambda}$	$k = 0$ (free-pinned half-beam) $B(\lambda) = 0$ or $\tan \lambda - \tanh \lambda = 0$ (Table 5.4)
		

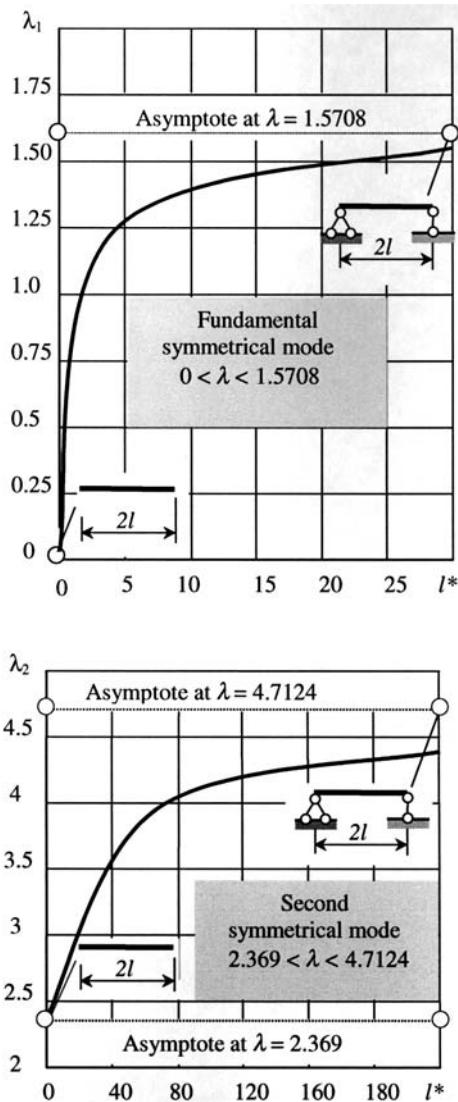

FIGURE 6.2. Symmetrical vibration. Parameters λ_1, λ_2 as a function of $k^* = kl^3/EI$.

Beam with two torsional spring supports (Fig. 6.6). The frequency vibration equals $\omega = \frac{\lambda}{l^2} \sqrt{\frac{EI}{m}}$, where λ is a root of the frequency equation

$$2\lambda^2 \tan \lambda \tanh \lambda + \lambda \left(\frac{k_1 l}{EI} + \frac{k_2 l}{EI} \right) (\tan \lambda - \tanh \lambda) + \frac{k_1 l k_2 l}{EI EI} \left(1 - \frac{1}{\cos \lambda \cosh \lambda} \right) = 0 \quad (6.2)$$

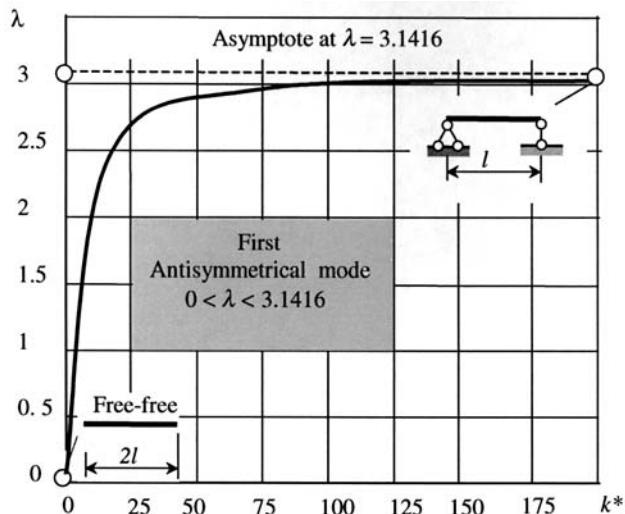

FIGURE 6.3. Antisymmetrical vibration. Parameter λ as a function of $k^* = kl^3/EI$.

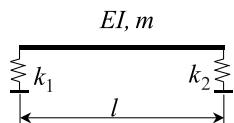

FIGURE 6.4. Design diagram.

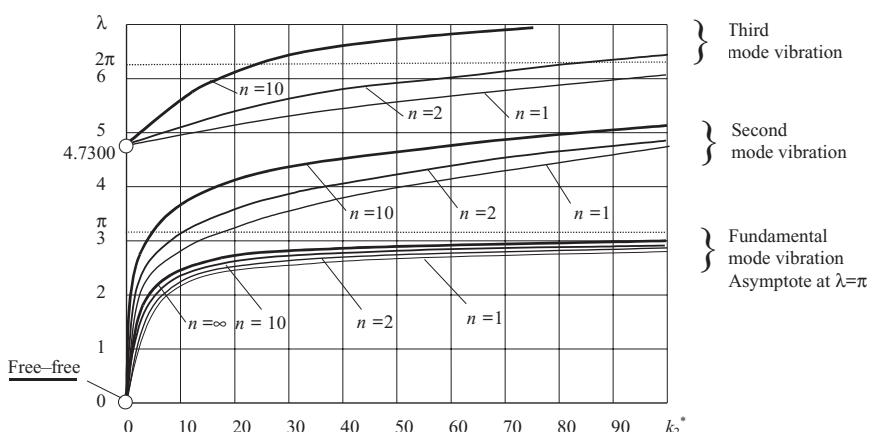

FIGURE 6.5. Fundamental, second and third modes of vibration. Parameters λ_1 , λ_2 and λ_3 as a function of $k_2^* = k_2 l^3/EI$ and parameter $n = k_1/k_2$.

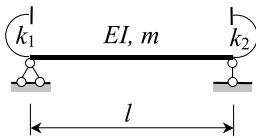

FIGURE 6.6. Design diagram and notation.

Special cases are presented in Table 6.4.

TABLE 6.4 One-span beams with torsional spring supports: frequency equation for limiting cases

	Design diagram	Frequency equation
Elastic clamped-pinned beam $k_2 = 0$		$2\lambda \tan \lambda \tanh \lambda + \frac{k_1 l}{EI}(\tan \lambda - \tanh \lambda) = 0$
Elastic clamped-clamped beam $k_2 = \infty$		$-\lambda(\tan \lambda - \tanh \lambda) + \frac{k_1 l}{EI}\left(1 - \frac{1}{\cos \lambda \cosh \lambda}\right) = 0$
Pinned-pinned beam $k_1 = k_2 = \infty$		$\sin \lambda = 0$
Clamped-clamped beam $k_1 = k_2 = \infty$		$\cos \lambda \cosh \lambda - 1 = 0$
Clamped-pinned beam $k_1 = \infty, k_2 = 0$		$\tan \lambda - \tanh \lambda = 0$

Frequency parameters λ for beams with two different torsional spring supports at the ends and for fundamental and higher mode vibrations are presented in Table 6.5.

Dimensionless parameters are

$$k_1^* = \frac{k_1 l}{EI}, k_2^* = \frac{k_2 l}{EI}.$$

The bold data present two limiting cases: (1) pinned-pinned beam and (2) Clamped-clamped beam (Hibbeler, 1975).

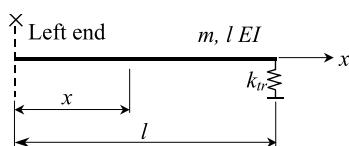

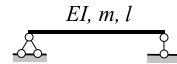

6.2 BEAMS WITH A TRANSLATIONAL SPRING AT THE FREE END

A beam with typical boundary conditions at the left-hand end and an elastic spring support at the right-hand end is shown in Fig. 6.7.

(1) and (2) denote pinned-pinned and clamped-clamped beams, respectively.

**FIGURE 6.7.** Design diagram; left end of the beam is free,
or pinned, or clamped.

The frequency of vibration equals $\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$, $m = \rho A$, where λ is a root of the frequency equation. The exact solution of the eigenvalue and eigenfunction problem for beams with different boundary conditions at the left-hand end and translational spring support at the right-hand end are presented in Table 6.6 (Anan'ev, 1946; Gorman, 1975).

Dimensionless parameters are

$$k_{tr}^* = \frac{k_{tr} l^3}{EI}, \quad \xi = \frac{x}{l}$$

TABLE 6.6. Frequency equation and mode shape of vibration for beams with translational spring support at right end

Left end	Frequency equation		Mode shape $X(\xi)$	Parameter γ
	Trigonometric-hyperbolic functions	Krylov-Duncan functions		
Free	$k_{tr}^* = \lambda^3 \frac{1 - \cosh \lambda \cos \lambda}{\cosh \lambda \sin \lambda - \sinh \lambda \cos \lambda}$	$\sinh \lambda \xi + \frac{\sin \lambda}{\sinh \lambda} \sin \lambda \xi + \gamma \left[\cosh \lambda \xi + \frac{-(\cosh \lambda - \cos \lambda)}{\sinh \lambda} \sinh \lambda \xi \right]$	$\sin \lambda - \sinh \lambda$	$\frac{\sin \lambda - \sinh \lambda}{\cosh \lambda - \cos \lambda}$
Pinned	$k_{tr}^* = \lambda^3 \frac{U^2 - TV}{TU - SV}$		$\sin \lambda \xi + \gamma \sinh \lambda \xi$	$\frac{\sin \lambda}{\sinh \lambda}$
Clamped	$k_{tr}^* = \lambda^3 \frac{\sin \lambda \cosh \lambda - \cos \lambda \sinh \lambda}{2 \sin \lambda \sinh \lambda}$	$\sinh \lambda \xi - \sin \lambda \xi + \gamma (\cosh \lambda \xi - \cos \lambda \xi)$	$\frac{\sin \lambda + \sinh \lambda}{\cos \lambda + \cosh \lambda}$	
	$k_{tr}^* = \lambda^3 \frac{TU - SV}{T^2 - V^2}$	$\frac{S^2 - VT}{TU - SV}$		

The frequency equations may also be presented in terms of Hohenemser-Prager functions (Section 4.5).

TABLE 6.7. Frequency equation for special cases

Left end	Parameter		Frequency equation	Related tables
	k_{tr}	(right end)		
Free	$k_{tr} = 0$	Free-free	$\cos \lambda \cosh \lambda - 1 = 0$	5.3
	$k_{tr} = \infty$	Free-pinned	$\sin \lambda \cosh \lambda - \sinh \lambda \cos \lambda = 0$	5.3; 6.4
Pinned	$k_{tr} = 0$	Pinned-free	$\sin \lambda \cosh \lambda - \sinh \lambda \cos \lambda = 0$	5.3; 6.4
	$k_{tr} = \infty$	Pinned-pinned	$\sin \lambda = 0$	5.3; 6.4

	$k_{tr} = \infty$	Clamped-pinned	$\sin \lambda \cosh \lambda - \sinh \lambda \cos \lambda = 0$	5.3; 6.4

Numerical Results. Some numerical results for first and second frequencies of vibration are presented below (Anan'ev, 1946).

6.2.1 Beam free at one end and with translational spring support at the other

Design diagram and frequency parameters λ_1 and λ_2 as a function of $k^* = kl^3/EI$ are presented in Figs. 6.8(a) and (b), respectively.

Special cases

1. Free-free beam ($k = 0$). Frequency equation is $D(\lambda) = 0 \rightarrow \cosh \lambda \cos \lambda = 1$.
2. Free-pinned beam ($k = \infty$). Frequency equation is $B(\lambda) = 0 \rightarrow \tan \lambda - \tanh \lambda = 0$.

6.2.2 Beam pinned at one end, and with translational spring support at the other

Design diagram and frequency parameters λ_1 and λ_2 as a function of $k^* = kl^3/EI$ are presented in Figs. 6.9(a) and (b), respectively.

Special cases

1. Pinned-pinned beam ($k = \infty$). Frequency equation is $S_1(\lambda) = 0 \rightarrow \sin \lambda = 0$ (see table 5.3).
2. Pinned-free beam ($k = 0$). Frequency equation is $B(\lambda) = 0 \rightarrow \tan \lambda - \tanh \lambda = 0$ (see table 5.3).

6.2.3 Beam clamped at one end and with a translational spring at the other

Design diagram and frequency parameters λ_1 and λ_2 as a function of $k^* = kl^3/EI$ are presented in Figs. 6.10(a) and (b), respectively.

Table 6.8 presents parameters λ_1 and λ_2 as a function of $k^* = kl^3/EI$.

TABLE 6.8. First and second frequency parameter for cantilevered beams with transitional spring support at the end

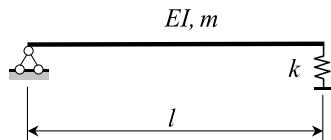

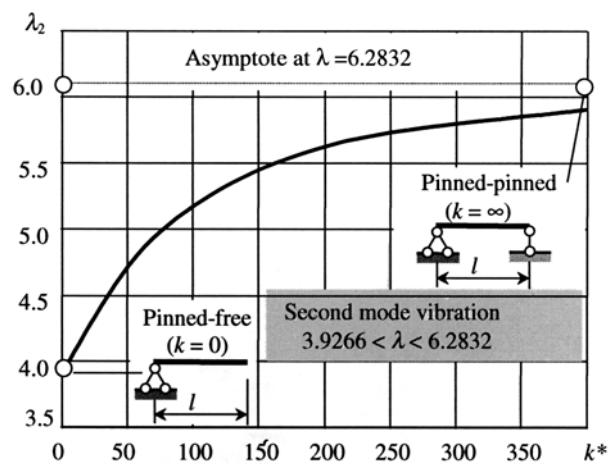

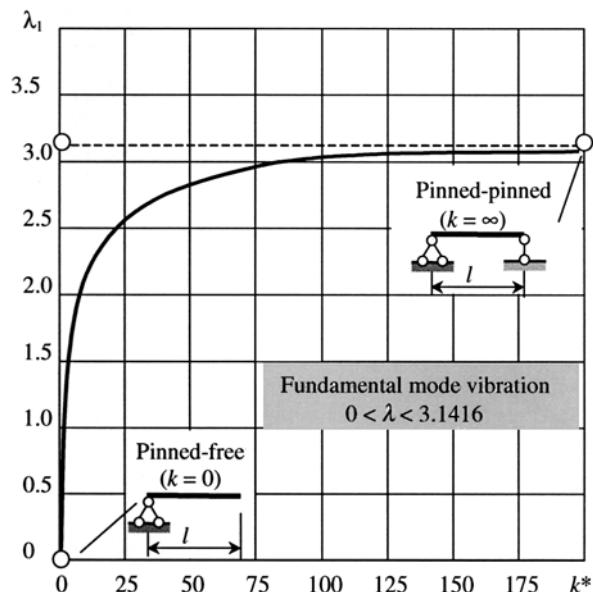

FIGURE 6.9(a). Design diagram.

FIGURE 6.9(b). Parameters λ_1 and λ_2 as a function of $k^* = kl^3/EI$.

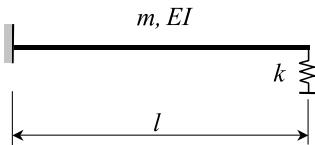

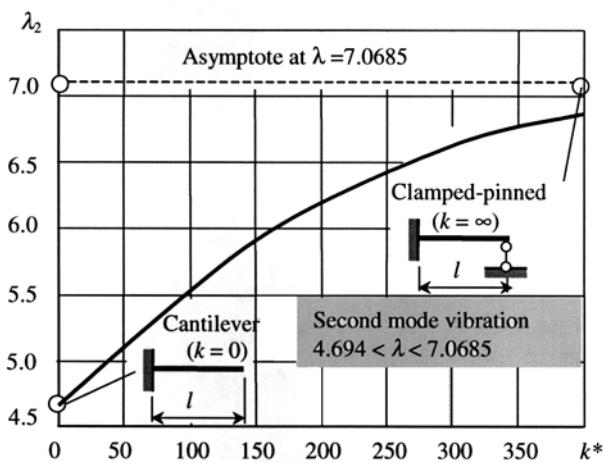

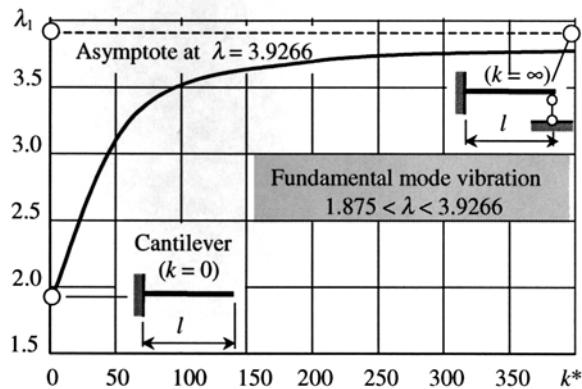

FIGURE 6.10(a). Design diagram.

FIGURE 6.10(b). Parameters λ_1 and λ_2 as a function of $k^* = kl^3/EI$.

Special cases

1. Clamped-free beam ($k = 0$). Frequency equation is $\cosh \lambda \cos \lambda = -1$ (see table 5.3).
2. Clamped-pinned beam ($k = \infty$). Frequency equation is $\tanh \lambda = \tan \lambda$ (see table 5.3).

6.2.4 Beam clamped at one end and with translational spring along the span

The design diagram is presented in Fig. 6.11.

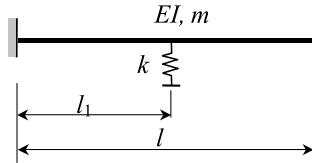

FIGURE 6.11. Design diagram.

The frequency vibration equals $\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$. Here, λ is a root of the frequency equation

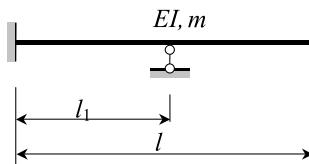

$$\begin{aligned} S^2(\lambda) - T(\lambda)V(\lambda) - \frac{1}{\lambda^3}k^*S[\lambda(1-l^*)]\{S(\lambda)V(\lambda l^*) - T(\lambda)U(\lambda l^*)\} \\ - \frac{1}{\lambda^3}k^*T[\lambda(1-l^*)]\{S(\lambda)U(\lambda l^*) - V(\lambda)V(\lambda l^*)\} = 0 \end{aligned}$$

where $S(\lambda)$, $T(\lambda)$, $U(\lambda)$ and $V(\lambda)$ are Krylov-Duncan functions.

Numerical results for specific values of $l^* = \frac{l_1}{l}$ and $k^* = \frac{kl^3}{EI}$ are presented in Table 6.12.

Special cases

1. Clamped-pinned beam with overhang ($k = \infty$)

$$\frac{S[\lambda(1-l^*)]}{T[\lambda(1-l^*)]}\{S(\lambda)V(\lambda l^*) - T(\lambda)U(\lambda l^*)\} + \{S(\lambda)U(\lambda l^*) - V(\lambda)V(\lambda l^*)\} = 0$$

2. Cantilever beam with translational spring at the free end ($l_1 = l$; $l^* = 1$)

$$k_{tr}^* = \lambda^3 \frac{S^2(\lambda) - V(\lambda)T(\lambda)}{S(\lambda)V(\lambda) - T(\lambda)U(\lambda)} \text{ or } k_{tr}^* = \lambda^3 \frac{\cosh \lambda \cos \lambda + 1}{\sinh \lambda \cos \lambda - \cosh \lambda \sin \lambda} \text{ (see section 6.2.3)}$$

3. Clamped-pinned beam without overhang ($k = \infty$ and $l^* = 1$)

$$S(\lambda)V(\lambda) - T(\lambda)U(\lambda) = 0 \text{ or } \tan \lambda - \tanh \lambda = 0 \text{ and } \lambda = 3.9266 \text{ (see table 5.3)}$$

4. Cantilever beam ($l^* = 0$ or $k = 0$)

$$S^2(\lambda) - T(\lambda)V(\lambda) = 0 \text{ or } \cosh \lambda \cos \lambda + 1 = 0 \text{ and } \lambda = 1.875 \text{ (see table 5.3)}$$

Example. Calculate the stiffness parameter k^* (l , l_1 and EI are given), which leads to frequency parameter $\lambda = 3.0$, if $l^* = 0.8$.

Solution. Frequency of vibration may be rewritten in the following form with respect to parameter k^*

$$k^* = \frac{\lambda^3 [S^2(\lambda) - T(\lambda)V(\lambda)]}{S[\lambda(1 - l^*)]\{S(\lambda)V(\lambda l^*) - T(\lambda)U(\lambda l^*)\} + T[\lambda(1 - l^*)]\{S(\lambda)U(\lambda l^*) - V(\lambda)V(\lambda l^*)\}}$$

A table of Krylov-Duncan functions is presented in Section 4.1.

If $\lambda = 3.0$ and $l^* = 0.8$, then

$$k^* = \frac{3^3[4.53883^2 - 5.07919 \times 4.93838]}{1.00540\{4.53883 \times 2.39539 - 5.07919 \times 3.14717\} + \dots} \\ \dots + 0.60074\{4.53883 \times 3.14717 - 4.93838 \times 2.39539\} \\ k^* = 33.013$$

Some numerical results are presented below.

6.3 BEAMS WITH TRANSLATIONAL AND TORSIONAL SPRINGS AT ONE END

A beam with typical boundary conditions at the left-hand end and elastic spring support at the right-hand end is shown in Fig. 6.12.

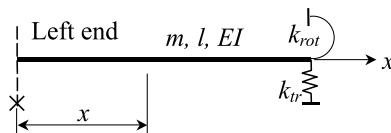

FIGURE 6.12. Design diagram: the left end of the beam is free, or pinned, or clamped.

Natural frequency of vibration is

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}, \quad m = \rho A$$

where λ is a root of the frequency equation.

The exact solution of the eigenvalue and eigenfunction problem (frequency equation and mode shape vibration) for beams with a classical boundary condition at the left-hand end and elastic supports at right-hand end are presented in Table 6.9 (Anan'ev, 1946; Weaver *et al.*, 1990; Gorman, 1975); Special cases are presented in Table 6.10. Non-dimensional parameters, used for the exact solution are:

$$k_{\text{rot}}^* = \frac{k_{\text{rot}}l}{EI}, \quad k_{\text{tr}}^* = \frac{k_{\text{tr}}l^3}{EI}, \quad \xi = \frac{x}{l}, \quad 0 \leq \xi \leq 1$$

6.3.1 Beam free at one end and with translational and rotational spring support at the other (Fig. 6.13)

Natural frequency vibration is $\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$, where λ is a root of the frequency equation.

The frequency equation may be presented in the following forms (Anan'ev, 1946; Gorman, 1975).

Form 1

$$k_{\text{tr}}^{*2} + k_{\text{tr}}^{*} \frac{\lambda \frac{k_{\text{tr}}^{*}}{k_r^{*}} (\sinh \lambda \cos \lambda - \cosh \lambda \sin \lambda) - \lambda^3 (\sin \lambda \cosh \lambda + \cos \lambda \sinh \lambda)}{1 + \cosh \lambda \cos \lambda} + \lambda^4 \frac{k_{\text{tr}}^{*} 1 - \cosh \lambda \cos \lambda}{k_r^{*} 1 + \cosh \lambda \cos \lambda} = 0$$

where dimensionless parameters are

$$k_r^{*} = \frac{k_r l}{EI}, \quad k_{\text{tr}}^{*} = \frac{k_{\text{tr}} l^3}{EI}, \quad \xi = \frac{x}{l}$$

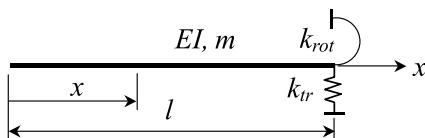

FIGURE 6.13. Design diagram.

Form 2

$$k_{\text{tr}}^* = \frac{\lambda^3 [k_r^* A(\lambda) + \lambda D(\lambda)]}{k_r^* E(\lambda) - \lambda B(\lambda)}$$

where A , B , E and D are Hohenemser-Prager functions.

Mode shape

$$X(\xi) = \sin \lambda \xi + \sinh \lambda \xi + \gamma (\cos \lambda \xi + \cosh \lambda \xi)$$

where

$$\gamma = \frac{\lambda^3 (\cos \lambda - \cosh \lambda) + k_{\text{tr}}^* (\sin \lambda + \sinh \lambda)}{\lambda^3 (\sin \lambda + \sinh \lambda) - k_{\text{tr}}^* (\cos \lambda + \cosh \lambda)}, \quad \xi = \frac{x}{l}$$

Example. Calculate the stiffness of rotational spring support k_{rot}^* , which leads to the fundamental frequency parameter $\lambda = 1.5$, if the stiffness of the translational spring support is $k_{\text{tr}}^* = 50$.

Solution. The frequency equation may be rewritten in the following form with respect to dimensionless stiffness parameter k_{rot}^* . The table of Hohenemser-Prager functions is presented in Chapter 4.

$$k_{\text{rot}}^* = \frac{\lambda^4 D(\lambda) + k_{\text{tr}}^* \lambda B(\lambda)}{k_{\text{tr}}^* E(\lambda) - \lambda^3 A(\lambda)} = \frac{1.5^4 \times (-0.83360) + 50 \times 1.5 \times 2.19590}{50 \times 1.16640 - 1.5^3 \times 2.49714} = 3.216$$

TABLE 6.11. Special cases

No.	Beam type	Stiffness parameters at right end	Frequency equation	Related Tables
1		$k_{\text{tr}}^* = 0$ and $k_r^* = 0$	$1 - \cosh \lambda \cos \lambda = 0$	5.3
2		$k_r^* = 0$	$k_{\text{tr}}^* + \lambda^3 \frac{1 - \cosh \lambda \cos \lambda}{\sinh \lambda \cos \lambda - \cosh \lambda \sinh \lambda} = 0$	6.3
3		$k_{\text{tr}}^* = 0$	$k_{\text{rot}}^* = \lambda \frac{1 - \cosh \lambda \cos \lambda}{\cosh \lambda \sinh \lambda + \cos \lambda \sinh \lambda}$	6.3
4		$k_{\text{tr}}^* = \infty$ and $k_r^* = 0$	$\tan \lambda - \tanh \lambda = 0$	5.3
5		$k_{\text{tr}}^* = 0$ and $k_r^* = \infty$	$\tan \lambda + \tanh \lambda = 0$	5.3
6		$k_{\text{tr}}^* = \infty$ and $k_r^* = \infty$	$1 + \cosh \lambda \cos \lambda = 0$	5.3
7		$k_r^* = \infty$	$k_{\text{tr}}^* = \lambda^3 \frac{\sin \lambda \cosh \lambda + \cos \lambda \sinh \lambda}{1 + \cos \lambda \cosh \lambda}$	6.5
8		$k_{\text{tr}}^* = \infty$	$k_{\text{rot}}^* + \lambda \frac{\sinh \lambda \cos \lambda - \cosh \lambda \sinh \lambda}{1 + \cosh \lambda \cos \lambda} = 0$	6.4

6.3.2 Beam free at one end and with rotational spring support at the other

The design diagram is presented in Fig. 6.14(a).

The natural frequency of vibration is $\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$, $m = \rho A$, where λ is a root of the frequency equation, which may be presented in the following forms (Anan'ev, 1946)

$$\text{Form 1: } \frac{k_{\text{rot}}l}{EI} = -\lambda \frac{D(\lambda)}{A(\lambda)}$$

$$\text{Form 2: } \frac{k_{\text{rot}}l}{EI} = -\lambda \frac{T(\lambda)V(\lambda) - U^2(\lambda)}{S(\lambda)T(\lambda) - U(\lambda)V(\lambda)}$$

$$\text{Form 3: } \frac{k_{\text{rot}}l}{EI} = -\lambda \frac{\cosh \lambda \cos \lambda - 1}{\cosh \lambda \sin \lambda + \sinh \lambda \cos \lambda}$$

Frequency parameters λ_1 and λ_2 for first and second modes of vibration as a function of $k_{\text{rot}}^* = k_{\text{rot}} \cdot l/EI$ are presented in Fig. 6.14(b).

Special cases

1. Free-free beam ($k_{\text{rot}} = 0$). Frequency equation is $D(\lambda) = 0 \rightarrow \cosh \lambda \cos \lambda = 1$ (see Table 5.3).
2. Free-sliding beam ($k_{\text{rot}} = \infty$). Frequency equation is $A(\lambda) = 0 \rightarrow \tanh \lambda + \tan \lambda = 0$ (Table 5.3).

6.3.3 Beam clamped at one end with translational and rotational springs supported along the span

The design diagram is presented in Fig. 6.15.

The natural frequency of vibration is

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}, \quad m = \rho A$$

where frequency parameters λ , in terms of spacing of support ul , mode number, stiffness parameters $k_1 = \frac{k_{\text{tr}}l^3}{EI}$ and $k_2 = \frac{k_{\text{rot}}l}{EI}$ are presented in Table 6.12 (Lau, 1984).

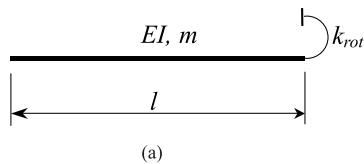

FIGURE 6.14(a). Design diagram.

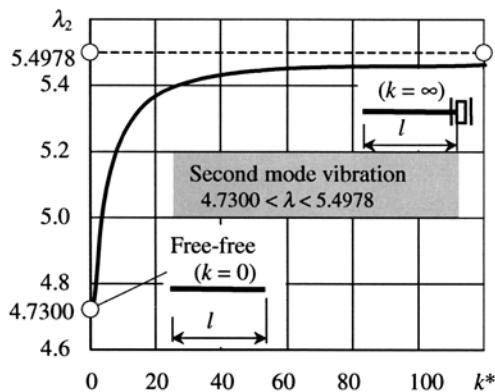

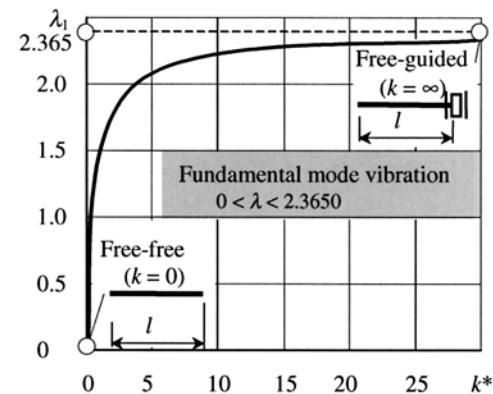

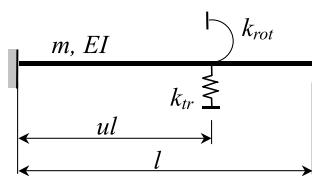

FIGURE 6.14(b). Parameters λ_1 and λ_2 as a function of $k^* = k_{\text{rot}}l/EI$.

(1) Bold results are presented for a cantilever beam ($k_1 = k_2 = 0$) and a clamped-pinned beam ($k_1 = \infty, k_2 = 0$).

(2) The shape mode expressions are presented in Lau (1984).

6.4 BEAMS WITH A TORSIONAL SPRING AT THE PINNED END

A beam with typical boundary conditions at the left-hand end and elastic spring support at the right-hand end is shown in Fig. 6.16.

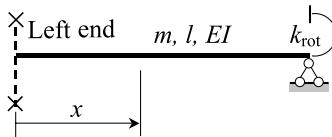

FIGURE 6.16. Design diagram: left-hand end of the beam is free, or pinned, or clamped.

The natural frequency of vibration is

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}, \quad m = \rho A$$

where λ is a frequency parameter.

The exact solution of the eigenvalue and eigenfunction problem (frequency equation and mode shape vibration) for beams with a classical boundary condition at the left-hand end and elastic supports at right-hand end are presented in Table 6.13 (Anan'ev, 1946;

Weaver *et al.*, 1990; Gorman, 1975); Special cases are presented in Table 6.14. Dimensionless parameters are $k_{\text{rot}}^* = \frac{k_{\text{rot}}l}{EI}$ and $\xi = \frac{x}{l}, 0 \leq \xi \leq 1$.

Example. The clamped-pinned beam has a rotational spring at the pinned support. Calculate the frequency vibration and compile the expression for mode shape.

Solution. Let parameter

$$k_{\text{rot}}^* = \frac{k_{\text{rot}}l}{EI} = 3.08$$

The root of the frequency equation

$$k^* = \lambda \frac{\sin \lambda \cosh \lambda - \sinh \lambda \cos \lambda}{\cos \lambda \cosh \lambda - 1}$$

is $\lambda = 4.20$.

The frequency of vibration

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}} = \frac{4.2^2}{l^2} \sqrt{\frac{EI}{m}}, \quad m = \rho A.$$

Parameter

$$\gamma(4.2) = \frac{\sinh \lambda - \sin \lambda}{\cos \lambda - \cosh \lambda} = -1.01052$$

TABLE 6.13. Frequency equation and mode shape of vibration for beams with rotational spring support at the pinned end

Left end	Frequency equation*		Mode shape $X(\xi)$	Parameter γ
	(1) Trigonometric-hyperbolic functions	(2) Krylov-Duncan functions		
Free	$k_{\text{rot}}^* = \lambda \frac{\sin \lambda \cosh \lambda - \sinh \lambda \cos \lambda}{1 + \cos \lambda \cosh \lambda}$	$k_{\text{rot}}^* = \lambda \frac{TU - SV}{S^2 - TV}$	$-(\sin \lambda \xi + \sinh \lambda \xi) + \gamma(\cos \lambda \xi + \cosh \lambda \xi)$	$\frac{\sin \lambda + \sinh \lambda}{\cos \lambda + \cosh \lambda}$
Pinned	$k_{\text{rot}}^* = \lambda \frac{2 \sin \lambda \sinh \lambda}{\cos \lambda \sinh \lambda - \sin \lambda \cosh \lambda}$	$k_{\text{rot}}^* = -\lambda \frac{T^2 - V^2}{TU - SV}$	$\sin \lambda \xi + \gamma \sinh \lambda \xi$	$-\frac{\sin \lambda}{\sinh \lambda}$
Clamped	$k_{\text{rot}}^* = \lambda \frac{\sin \lambda \cosh \lambda - \sinh \lambda \cos \lambda}{\cos \lambda \cosh \lambda - 1}$	$k_{\text{rot}}^* = \lambda \frac{TU - SV}{TV - U^2}$	$\sinh \lambda \xi - \sin \lambda \xi + \gamma(\cosh \lambda \xi - \cos \lambda \xi)$	$\frac{\sin \lambda - \sinh \lambda}{\cosh \lambda - \cos \lambda}$

* The frequency equations may also be presented in terms of Hohenemser-Prager functions (Section 4.5).

Expressions for mode shape vibration and slope may be presented in the form

$$\begin{aligned} X(\xi) &= \sin \lambda \xi - \sinh \lambda \xi + \gamma (\cos \lambda \xi - \cosh \lambda \xi), \lambda = 4.2, \gamma = -1.01052, \\ X'(\xi) &= \lambda (\cos \lambda \xi - \cosh \lambda \xi) + \gamma \lambda (-\sin \lambda \xi - \sinh \lambda \xi), 0 \leq \xi \leq 1 \end{aligned}$$

TABLE 6.14. Special cases

Parameter	Beam type	Frequency equation	Related tables
$k_{\text{rot}} = 0$	Free-pinned	$\sin \lambda \cosh \lambda - \sinh \lambda \cos \lambda = 0$	5.3
	Pinned-pinned	$\sin \lambda = 0$	5.3
	Clamped-pinned	$\sin \lambda \cosh \lambda - \sinh \lambda \cos \lambda = 0$	5.3
$k_{\text{rot}} = \infty$	Free-clamped	$1 + \cos \lambda \cosh \lambda = 0$	5.3; 4.4; 4.5
	Pinned-clamped	$\tan \lambda - \tanh \lambda = 0$	5.3
	Clamped-clamped	$1 - \cos \lambda \cosh \lambda = 0$	5.3; 4.4; 4.5

6.4.1 Numerical results

Some numerical results are presented below (Anan'ev, 1946).

Beam free at one end and pinned with a rotational spring support at the other. The design diagram and frequency parameters λ_1 and λ_2 for the fundamental and second mode of vibration, as a function of $k_{\text{rot}}^* = \frac{k_{\text{rot}} l}{EI}$, are presented in Figs. 6.17(a) and (b).

Special cases

1. Pinned-free beam ($k_{\text{rot}} = 0$): $\tan \lambda - \tanh \lambda = 0$ (see table 5.3).
2. Clamped-free beam ($k_{\text{rot}} = \infty$): $\cosh \lambda \cos \lambda + 1 = 0$ (see table 5.3).

Beam pinned at one end and pinned with a torsional spring support at the other. The design diagram and frequency parameters λ_1 and λ_2 for the fundamental and second mode of vibration, as a function of $k^* = \frac{k_{\text{rot}} l}{EI}$, are presented in Figs. 6.18(a) and (b).

Special cases

1. Pinned-pinned beam ($k_{\text{rot}} = 0$): Frequency equation is $S_1(\lambda) = 0 \rightarrow \sin \lambda = 0$ (see table 5.3).
2. Pinned-clamped beam ($k_{\text{rot}} = \infty$): Frequency equation is $B(\lambda) = 0 \rightarrow \tan \lambda - \tanh \lambda = 0$ (see table 5.3).

Beam clamped at one end and pinned with a torsional spring support at the other. The design diagram and frequency parameters λ_1 and λ_2 for the fundamental and second mode of vibration, as a function of $k_r^* = \frac{k_r l}{EI}$, are presented in Figs. 6.19(a) and (b).

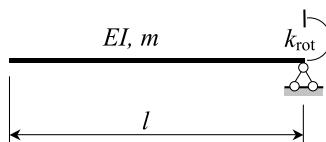

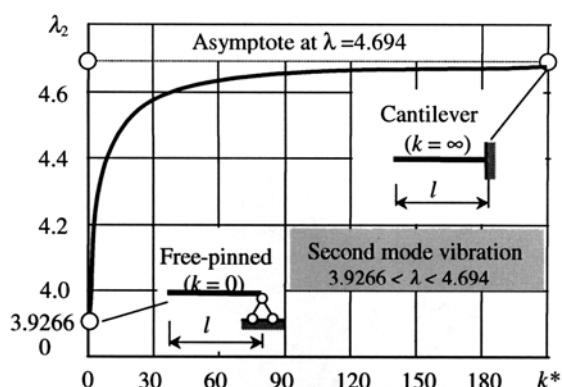

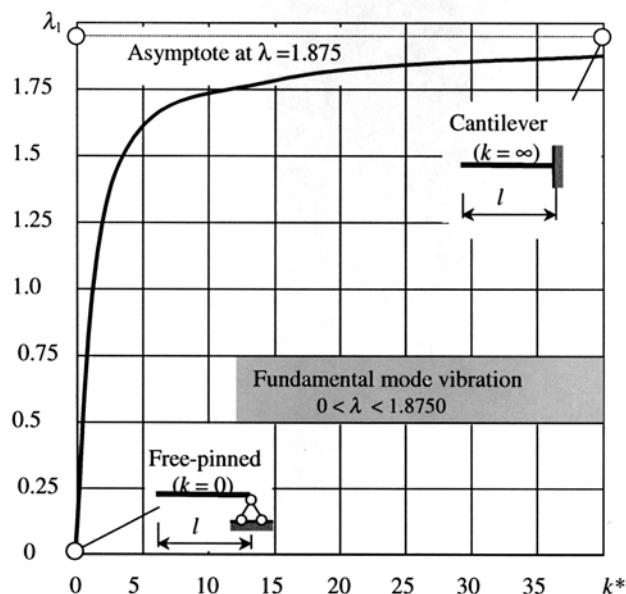

FIGURE 6.17(a). Design diagram.

FIGURE 6.17(b). Parameters λ_1 and λ_2 as a function of $k^* = k_{\text{rot}}l/EI$.

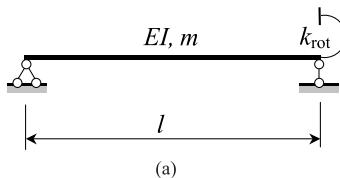

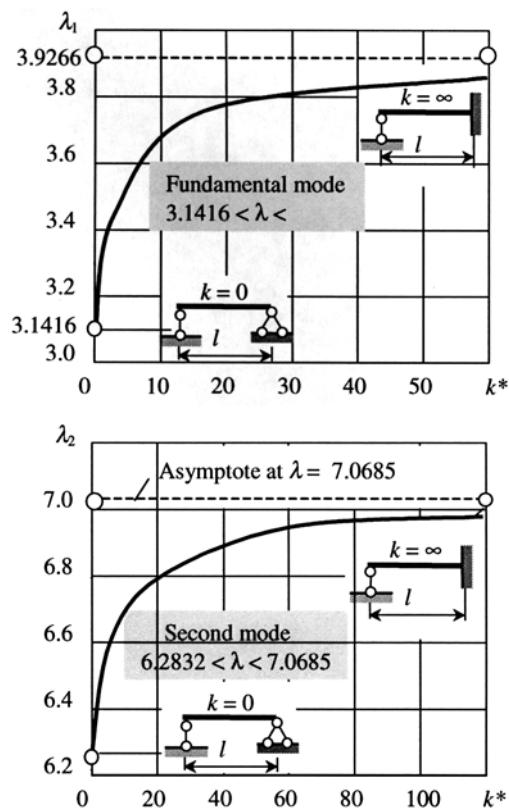

FIGURE 6.18(a). Design diagram.

FIGURE 6.18(b). Parameters λ_1 and λ_2 as a function of $k^* = k_{\text{rot}}l/EI$.

Special cases

1. Clamped-pinned beam ($k_{\text{rot}} = 0$). Frequency equation is $\tan \lambda - \tanh \lambda = 0$ (see table 5.3).
2. Clamped-clamped beam ($k_{\text{rot}} = \infty$). Frequency equation is $\cosh \lambda \cos \lambda = 1$ (see table 5.3).

6.5 BEAMS WITH SLIDING-SPRING SUPPORTS

Exact solutions of the eigenvalue problem for beams with sliding-spring supports are presented in Table 6.15 (Anan'ev, 1946).

Frequency of vibration is $\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$, $m = \rho A$, where λ is a root of the frequency equation.

Stiffness parameters are $k_1^* = \frac{k_1 l^3}{EI}$, $k_2^* = \frac{k_2 l^3}{EI}$.

6.5.1 Numerical results

Some numerical results are presented below (Anan'ev, 1946).

Beam with a sliding spring support at one end and free at the other. The design diagram and numerical results are presented in Fig. 6.20(a) and (b), respectively.

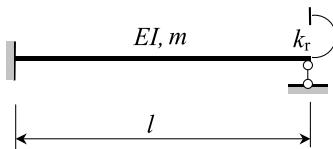

The natural frequency of vibration is $\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$, $m = \rho A$, where λ is a root of the frequency equation, which may be presented in different forms.

$$\begin{aligned} \text{Form 1. } \frac{kl^3}{EI} &= \lambda^3 \frac{A(\lambda)}{E(\lambda)} \\ \text{Form 2. } \frac{kl^3}{EI} &= \lambda^3 \frac{S(\lambda)T(\lambda) - U(\lambda)V(\lambda)}{S^2(\lambda) - T(\lambda)V(\lambda)} \\ \text{Form 3. } \frac{kl^3}{EI} &= \lambda^3 \frac{\cosh \lambda \sin \lambda + \sinh \lambda \cos \lambda}{\cosh \lambda \cos \lambda + 1} \end{aligned}$$

Special cases

1. Sliding-free beam ($k = 0$). Frequency equation is $A(\lambda) = 0 \rightarrow \tan \lambda + \tanh \lambda = 0$ (see table 5.3)
2. Clamped-free beam ($k = \infty$). Frequency equation is $E(\lambda) = 0 \rightarrow \cos \lambda \cosh \lambda + 1 = 0$ (see table 5.3).

Example. Consider a beam free at one end with a sliding spring support at the other. Calculate the stiffness parameter k^* that leads to a fundamental frequency parameter $\lambda = 1.4$.

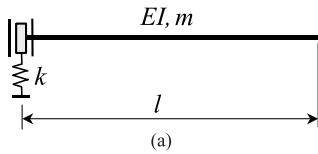

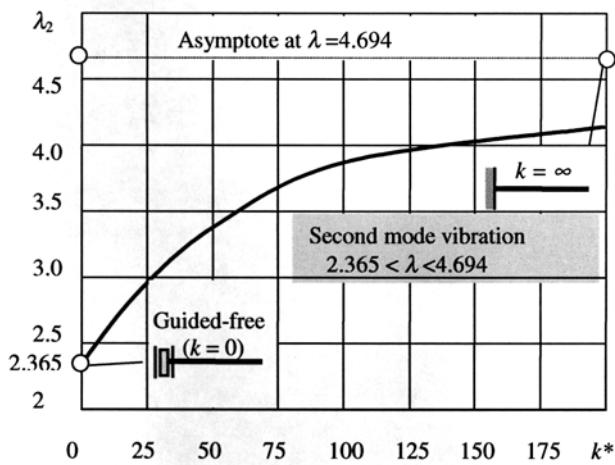

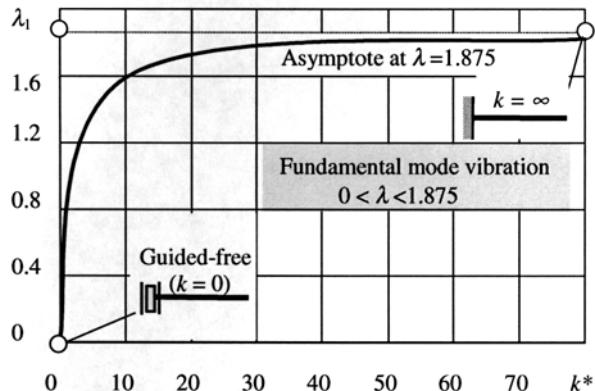

FIGURE 6.20(a). Design diagram.

FIGURE 6.20(b). Parameters λ_1 and λ_2 as a function of $k^* = kl^3/EI$.

Solution. According to Table 6.15, case 3, the required parameter is

$$k_{\text{tr}}^* = \lambda^3 \frac{A(\lambda)}{E(\lambda)} = 1.4^3 \times \frac{2.44327}{1.36558} = 4.909$$

Example. Consider a beam clamped at one end with a sliding spring support at the other. Calculate the stiffness parameter k^* , which leads to a fundamental frequency parameter $\lambda = 2.0$.

Solution. The stiffness parameter according to case 1, Table 4.4

$$k_{\text{tr}}^* = \lambda^3 \frac{A(\lambda)}{D(\lambda)} = 2^3 \times \frac{1.91165}{-2.56563}$$

is negative. So, for a given type of beam, the stiffness parameter $\lambda = 2.0$ is impossible to achieve. The minimum value of the parameter λ is 2.38 when Hohenemser-Prager functions A and D have the same sign. In this case

$$k_{\text{tr}}^* = \lambda^3 \frac{A(\lambda)}{D(\lambda)} = 2.38^3 \times \frac{-0.12644}{-4.94345} = 0.348$$

6.6 BEAMS WITH TRANSLATIONAL AND TORSIONAL SPRING SUPPORTS AT EACH END

The supports of the beam, which are shown in Fig. 6.21, are all elastic. The spring constants are k_1 and k_2 for the translational springs and k_3 and k_4 for the rotational springs. This means that the amount of force (moment) present is proportional to the amount of deflection (rotation):

$$\begin{aligned} V_a &= k_1 y(0, t) & V_b &= k_2 y(l, t) \\ M_a &= k_3 y'(0, t) & M_b &= k_4 y'(l, t) \end{aligned}$$

The frequency equation for the general case is presented below.

The natural frequency of vibration is $\omega = k^2 \sqrt{\frac{EI}{m}} = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$, where the frequency parameter, k , is a root of the frequency equation.

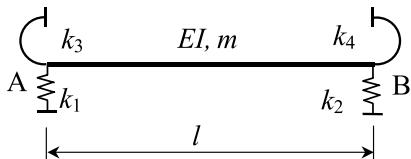

FIGURE 6.21. Beam with elastic supports.

The frequency equation for the general case is given below (Rogers, 1959; Weaver *et al.*, 1990; Maurizi *et al.*, 1991).

$$\begin{bmatrix} -k^3 & \frac{k_1}{EI} & k^3 & \frac{k_1}{EI} \\ -\frac{k_3}{EI} & -k & -\frac{k_3}{EI} & k \\ -k^3 \cos kl - \frac{k_2}{EI} \sin kl & k^3 \sin kl - \frac{k_2}{EI} \cos kl & k^3 \cosh kl - \frac{k_2}{EI} \sinh kl & k^3 \sinh kl - \frac{k_2}{EI} \cosh kl \\ -k \sin kl + \frac{k_4}{EI} \cos kl & -k \cos kl - \frac{k_4}{EI} \sin kl & k \sinh kl + \frac{k_4}{EI} \cosh kl & k \cosh kl + \frac{k_4}{EI} \sinh kl \end{bmatrix} = 0$$

Special cases are presented in Table 6.16.

TABLE 6.16. Special cases

Left End		Right End	
Stiffness	Boundary conditions	Stiffness	Boundary conditions
$k_1 = 0, k_3 = 0$	Free end	$k_2 = 0, k_4 = 0$	Free end
$k_1 = 0, k_3 = \infty$	Guided	$k_2 = 0, k_4 = \infty$	Guided
$k_1 = \infty, k_3 = 0$	Pinned	$k_2 = \infty, k_4 = 0$	Pinned
$k_1 = \infty, k_3 = \infty$	Clamped	$k_2 = \infty, k_4 = \infty$	Clamped

Example. Derive the frequency equation for a clamped-clamped beam (Fig. 6.22).

Solution. The frequency equation becomes

$$\begin{vmatrix} 0 & 1 & 0 & 1 \\ 1 & 0 & 1 & 0 \\ \sin kl & \cos kl & \sinh kl & \cosh kl \\ \cos kl & -\sin kl & \cosh kl & \sinh kl \end{vmatrix} = 0$$

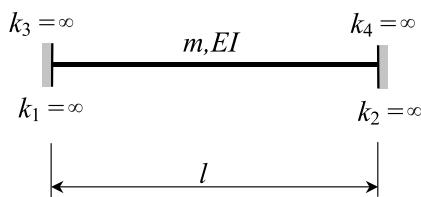

FIGURE 6.22. Design diagram.

We expand this determinant with respect to the first row to get

$$\begin{aligned} -1(\sinh^2 kl - \cosh^2 kl - \sin kl \cos kl + \cos kl \cosh kl) \\ - 1(\cos kl \cosh kl + \sin kl \sinh kl - \sin^2 kl - \cos^2 kl) = 0 \end{aligned}$$

Using the well-known trigonometric identities leads to the frequency equation

$$\cos kl \cosh kl = 1 \quad (\text{Table 5.3}).$$

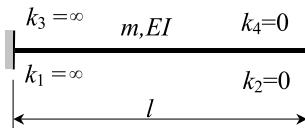

FIGURE 6.23. Design diagram.

Example. Derive the frequency equation for a clamped-free beam (Fig. 6.23).

Solution. The frequency equation becomes

$$\begin{vmatrix} 0 & 1 & 0 & 1 \\ 1 & 0 & 1 & 0 \\ -\cos kl & \sin kl & \cosh kl & \sinh kl \\ -\sin kl & -\cos kl & \sinh kl & \cosh kl \end{vmatrix} = 0$$

This determinant is expanded to yield the frequency equation $\cos kl \cosh kl = -1$ (Table 5.3).

Example. Derive the frequency equation for the free-free beam. All stiffnesses $k_i, i = 1, \dots, 4$ equal zero.

Solution. The frequency equation becomes

$$\begin{vmatrix} -1 & 0 & 1 & 1 \\ 0 & -1 & 0 & 1 \\ -\cos kl & \sin kl & \cosh kl & \sinh kl \\ -\sin kl & -\cos kl & \sinh kl & \cosh kl \end{vmatrix} = 0$$

The frequency equation is the same as that for a clamped-clamped beam.

6.7 FREE-FREE BEAM WITH TRANSLATIONAL SPRING SUPPORT AT THE MIDDLE SPAN

The design diagram is presented in Fig. 6.24(a).

The natural frequency of vibration is $\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$, $m = \rho A$, where λ is a root of the frequency equation, which may be presented in different forms (Anan'ev, 1946).

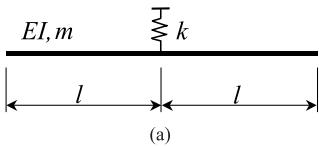

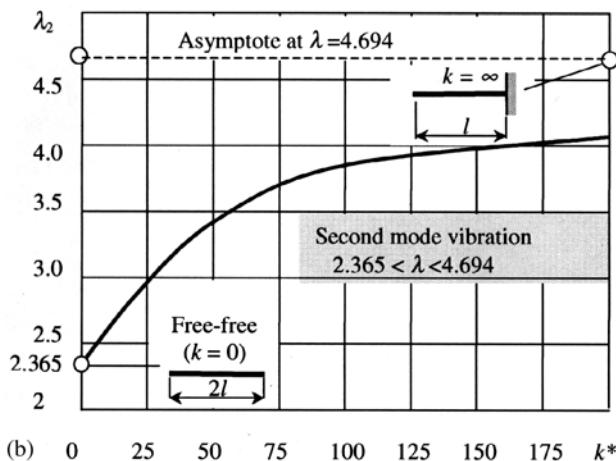

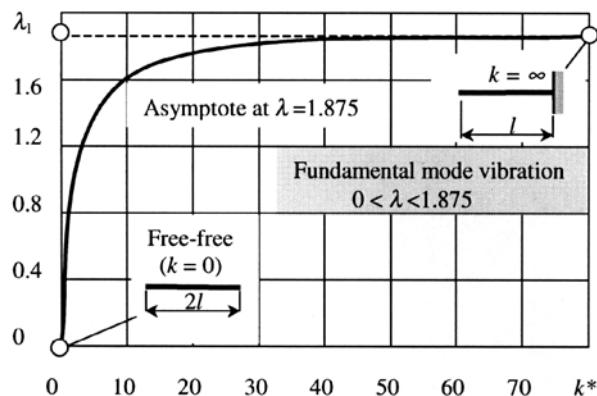

FIGURE 6.24(a). Design diagram.

FIGURE 6.24(b). Symmetrical mode of vibration: parameters λ_1 and λ_2 as a function of $k^* = kl^3/EI$.

Symmetrical vibration

$$\text{Form 1. } \frac{kl^3}{2EI} = \lambda^3 \frac{A(\lambda)}{E(\lambda)}$$

$$\text{Form 2. } \frac{kl^3}{2EI} = \lambda^3 \frac{\cosh \lambda \sin \lambda + \sinh \lambda \cos \lambda}{\cosh \lambda \cos \lambda + 1}$$

$$\text{Form 3. } \frac{kl^3}{2EI} = \lambda^3 \frac{(S(\lambda)T(\lambda) - U(\lambda)V(\lambda))}{S^2(\lambda) - T(\lambda)V(\lambda)}$$

Frequency parameters λ_1 and λ_2 for the fundamental and second mode of vibration as a function of $k^* = kl^3/2EI$ are shown in Fig. 6.24(b).

Antisymmetrical vibration. The frequency equation

$$B(\lambda) = 0 \rightarrow \cosh \lambda \sin \lambda - \sinh \lambda \cos \lambda = 0$$

or

$$T(\lambda)U(\lambda) - S(\lambda)V(\lambda) = 0$$

Frequency parameters are $\lambda_1 = 3.926$, $\lambda_2 = 7.0685$.

Special cases

1. Free-clamped ($k = \infty$). Frequency equation is $E(\lambda) = 0 \rightarrow \cos \lambda \cosh \lambda + 1 = 0$ (see table 5.3).
2. Free-free beam length of $2l$ ($k = 0$). Frequency equation is $\lambda = 0$, $A(\lambda) = 0$ (see table 5.3).

CHAPTER 7

BERNOULLI-EULER BEAMS WITH LUMPED AND ROTATIONAL MASSES

This chapter focuses on Bernoulli–Euler uniform one-span beams with lumped and rotational masses. Beams with classic and non-classic boundary conditions, as well as elastic translational and torsional supports, are presented. Fundamental characteristics such as frequency equations, natural frequencies of vibration and mode shape vibrations are presented. For many cases, the frequency equation is presented in the different forms that occur in scientific problems. The chapter contains a vast amount of numerical results.

NOTATION

A	Cross-sectional area
A, B, C, D, E, S_1	Hohenemser–Prager functions
E	Young's modulus
EI	Bending stiffness
g	Acceleration of gravity, $g = 9.8 \text{ m/s}^2$
I_z	Moment of inertia of a cross-section
J	Moment inertia of the lumped mass
J^*	Moment inertia ratio
k_n	Frequency parameter, $k_n = \sqrt[4]{\frac{m\omega^2}{EI}}, \lambda = kl$
$k_{\text{tr}}, k_{\text{rot}}$	Translational and rotational stiffness coefficients
$k_{\text{tr}}^*, k_{\text{rot}}^*$	Dimensionless translational and rotational stiffness coefficients
l	Length of the beam
M	Concentrated mass
q	Uniformly distributed load
S, T, U, V	Krylov–Duncan functions
x	Spatial coordinate
$X(x)$	Mode shape
x, y, z	Cartesian coordinates
α	Mass ratio

λ	Frequency parameter, $\lambda^4 EI = ml^4 \omega^2$
ξ	Dimensionless coordinate, $\xi = x/l$
ρ, m	Density of material and mass per unit length
ω	Natural frequency, $\omega^2 = \lambda^4 EI / ml^4$

7.1 SIMPLY SUPPORTED BEAMS

7.1.1 Beam with lumped mass at the middle-span

The design diagram is presented in Fig. 7.1(a).

Symmetric vibration (SV). The natural frequency of vibration is $\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$, $m = \rho A$, where λ is a root of the frequency equation, which may be presented in terms of Hohenemser-Prager's functions or in explicit form (Anan'ev, 1946).

$$\text{Form 1. } \frac{M}{2ml} = \frac{C(\lambda)}{\lambda B(\lambda)} \quad (7.1)$$

$$\text{Form 2. } \frac{M}{2ml} = \frac{1}{\lambda} \frac{2 \cosh \lambda \cos \lambda}{\cosh \lambda \sin \lambda - \sinh \lambda \cos \lambda} \quad (7.1a)$$

Frequency parameters as a function of mass ratio $\alpha = \frac{M}{2ml}$ is presented in Fig. 7.1(b).

Antisymmetric vibration (AsV). The frequency equation and the corresponding roots of the equation are

$$S_1(\lambda) = 0, \quad \lambda_1 = \pi, \quad \lambda_2 = 2\pi, \quad \lambda_3 = 3\pi, \dots \quad (7.2)$$

The band frequency spectrum for symmetric vibration and the discrete spectrum for antisymmetric vibration are presented in Fig. 7.2.

7.1.2 Beam with lumped mass along the span

The design diagram is presented in Fig. 7.3(a).

Natural frequency of vibration is $\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m(1+e)}}$, where λ is a root of the frequency equation, which may be presented in the following form (Morrow, 1906; Filippov, 1970):

$$2 \sin \lambda \sinh \lambda - a\lambda (\sin \lambda \xi_1 \sin \lambda \xi_2 \sinh \lambda - \sinh \lambda \xi_1 \sinh \lambda \xi_2 \sin \lambda) = 0 \quad (7.3)$$

The dimensionless parameters are

$$\begin{aligned} \xi_1 &= \frac{d}{l}; \quad \xi_2 = 1 - \xi_1 \\ \alpha &= \frac{M}{(1+e)ml}; \quad e = \frac{q}{g\rho A} \end{aligned}$$

Parameter λ^4 for fundamental mode of vibration is presented in Fig. 7.3(b).

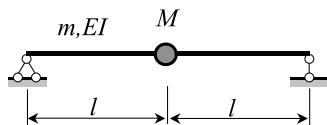

FIGURE 7.1(a). Design diagram.

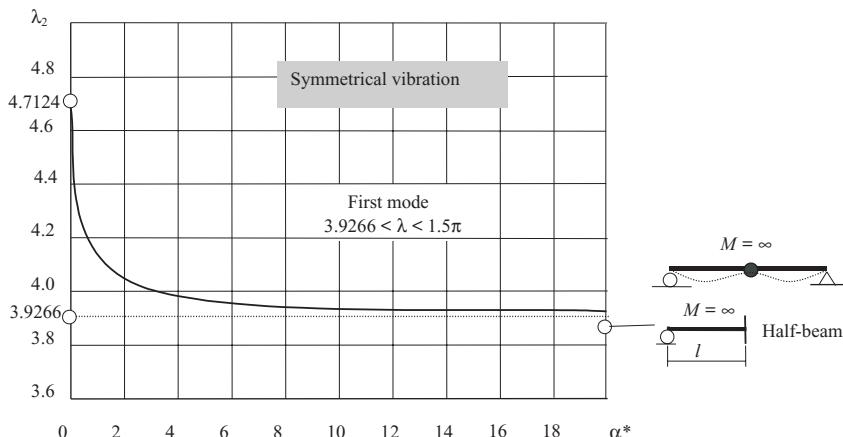

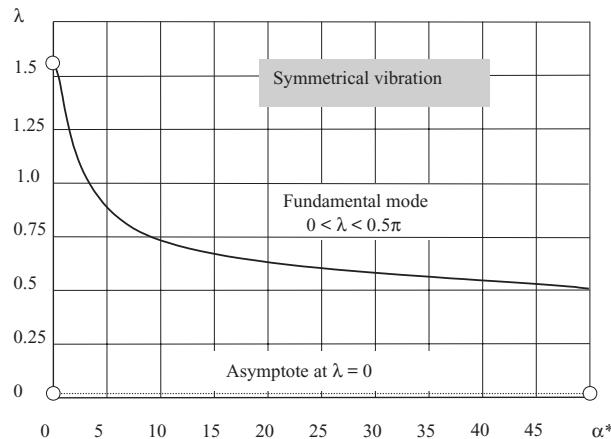

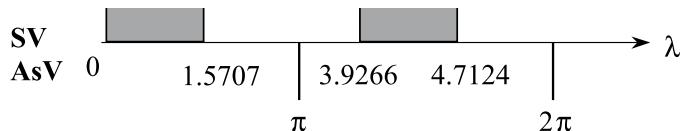

FIGURE 7.1(b). Beam with lumped mass at the middle span. Symmetrical mode of vibration. Parameters λ_1 and λ_2 are a function of mass ratio $\alpha = M/2l$.

FIGURE 7.2. Frequency spectrum for a pinned-pinned beam with lumped mass.

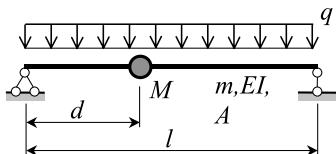

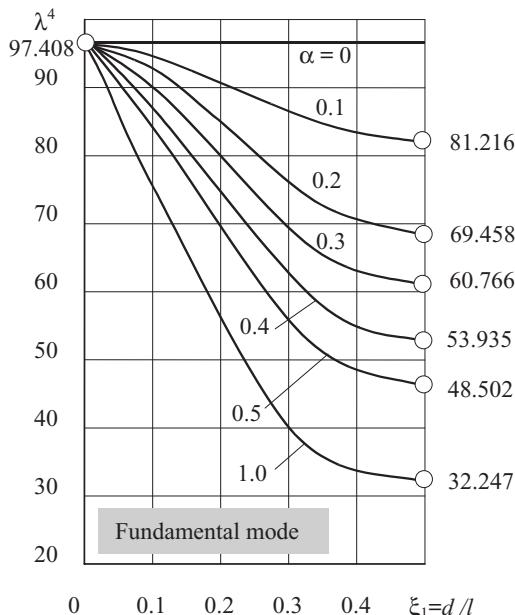

FIGURE 7.3(a). Design diagram.

FIGURE 7.3(b). Simply supported beam with lumped mass along the span. Frequency parameter λ^4 is a function of mass ratio α and spacing ξ_1 .

Special case. Lumped mass at the middle of the beam.

Symmetric vibration. The frequency equation is

$$\cosh \frac{\lambda}{2} \cos \frac{\lambda}{2} - \frac{\alpha \lambda}{4} \left(\cosh \frac{\lambda}{2} \sin \frac{\lambda}{2} - \sinh \frac{\lambda}{2} \cos \frac{\lambda}{2} \right) = 0 \quad (7.4)$$

Parameters λ for the fundamental frequency of vibration are listed in Table 7.1.

Antisymmetric vibration. The frequency equation and corresponding roots of the equation are

$$\sin \frac{\lambda}{2} = 0, \quad \lambda = 2n\pi, \quad n = 1, 2, 3, \dots$$

The expressions for mode shape vibration are presented in Section 7.6.

TABLE 7.1. Simply supported uniform beam with lumped mass at middle of the span: Frequency parameter λ for fundamental symmetric vibration

α	0.00	0.05	0.10	0.15	0.20	0.25	0.30	0.40	0.50	0.75
λ	3.142	3.068	3.002	2.942	2.887	2.838	2.792	2.710	2.639	2.496
α	1.0	2.0	4.0	6.0	8.0	10	15	20	40	60
λ	2.383	2.096	1.809	1.649	1.542	1.463	1.327	1.237	1.044	0.944

7.1.3 Beam with equal lumped masses

The design diagram of a symmetrical beam with lumped masses is presented in Fig. 7.4(a).

The natural frequency of vibration equals

$$\omega_i = \frac{\lambda_i^2}{l_1^2} \sqrt{\frac{EI}{m}} = \frac{(\lambda_i n)^2}{l^2} \sqrt{\frac{EI}{m}}$$

where λ_i are roots of the frequency equation.

Frequency equation. (Filippov, 1970)

$$D(\lambda) = \frac{\cos^2 \frac{v\pi}{n} - (\cosh \lambda + \cos \lambda) \cos \frac{v\pi}{n} + \cosh \lambda \cos \lambda}{\frac{\lambda}{2} \left[\cosh \lambda \sin \lambda - \sinh \lambda \cos \lambda + (\sinh \lambda - \sin \lambda) \cos \frac{v\pi}{n} \right]} = \frac{M}{2ml_1} \quad (7.5)$$

where n is a number of segments, $0 = 1, 2, 3, \dots$ are natural numbers. The curves $D(\lambda)$ for $n = 4$ are presented in Fig. 7.4(b). Parameters λ are the points of intersections of the line $n = M/2ml_1$ with curves $D(\lambda)$; the numbers $i = 1, 2, 3, \dots$ correspond to frequencies ω_i .

The relationship between number n of segments and number i of the frequencies is presented in Table 7.2.

Example. Calculate the natural frequencies of vibration for the uniform symmetrical simply supported beam with three equal point masses, shown in Fig. 7.5. Assume, that $ml_1 = 2M$.

Solution. The number of segments $n = 4$. Parameter $\frac{M}{2ml_1} = 1$.

The horizontal line $D(\lambda) = 1$ intersects the curves $D(\lambda)$ for $\frac{v}{n} = \frac{1}{4}; \frac{2}{4} = \frac{1}{2}; \frac{3}{4}$ at the following values of frequency parameters λ

i	1	2	3	4	5	6	7	8	9
λ	0.60	1.19	1.76	3.48	4.10	4.69	6.62	7.21	7.73

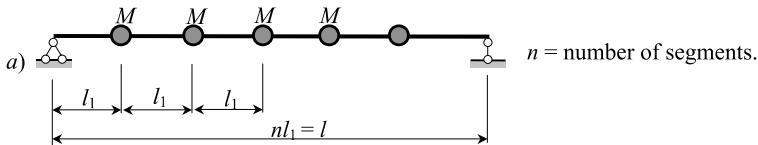

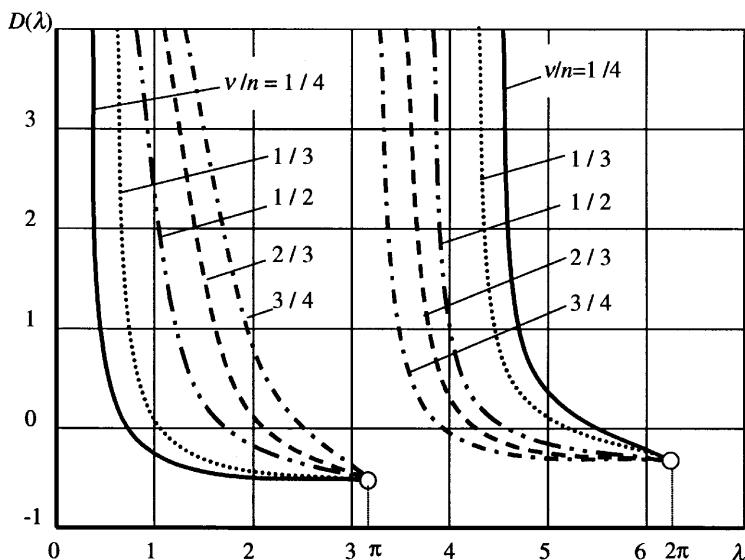

FIGURE 7.4(a). Simply supported beam with lumped masses.

FIGURE 7.4(b). Graph of $D(\lambda)$ for different v/n . Two groups of curves for $\lambda < \pi$, and $\pi < \lambda < 2\pi$. Third group for $\lambda > 2\pi$ is not shown; $\lambda = 1, 2, 3, \dots$ are natural numbers.TABLE 7.2. Simply supported symmetrical uniform beam with equal lumped masses: Additional parameters for graph $D(\lambda)$

Number n of segments	2	3	4	5
Parameters v/n of the curves	1/2	1/3, 2/3	1/4, 2/4 = 1/2, 3/4	1/5, 2/5, 3/5, 4/5
Number i of the frequencies	3	6	9	12

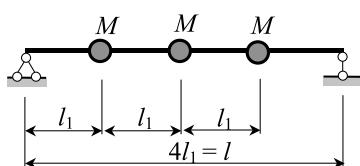

FIGURE 7.5. Simply supported beam with lumped masses.

Natural frequencies of vibration are

$$\omega_1 = \frac{0.6^2}{l_1^2} \sqrt{\frac{EI}{m}} = \frac{(0.6 \times 4)^2}{l^2} \sqrt{\frac{EI}{m}}, \quad \omega_2 = \frac{(1.19 \times 4)^2}{l^2} \sqrt{\frac{EI}{m}}, \dots$$

Example. Calculate the natural frequency of vibration for the uniform symmetrical beam with one point mass, shown in Fig. 7.6. Assume, that $ml_1 = M$.

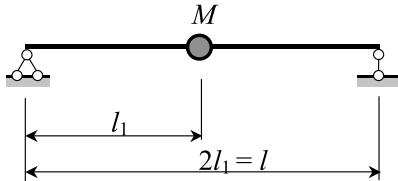

FIGURE 7.6. Simply supported beam with one point mass.

Solution. The number of segments $n = 2$. Parameter $\frac{M}{2ml_1} = 1$.

The horizontal line $D(\lambda) = 1$ intersects the curves $D(\lambda)$ for $\frac{v}{n} = \frac{1}{2}$ at $\lambda = 1.19, 4.10, 7.21$.

Consequently, the frequencies of vibration are

$$\omega_1 = \frac{(1.19 \times 2)^2}{l^2} \sqrt{\frac{EI}{m}} = \frac{2.38^2}{l^2} \sqrt{\frac{EI}{m}}, \quad \omega_2 = \frac{(4.10 \times 2)^2}{l^2} \sqrt{\frac{EI}{m}}, \quad \omega_3 = \frac{(7.21 \times 2)^2}{l^2} \sqrt{\frac{EI}{m}}$$

Parameter $\lambda = 1.19$ corresponds to symmetrical vibration with one half-wave;

Parameter $\lambda = 4.10$ corresponds to antisymmetrical vibration with two half-waves;

Parameter $\lambda = 7.21$ corresponds to symmetrical vibration with two half-waves.

7.1.4 Beam with the spring-mass at the middle of the span

The design diagram is presented in Fig. 7.7(a).

Natural frequency of vibration is $\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$, where λ is a root of the frequency equation.

Frequency equation for symmetrical vibration. (Anan'ev, 1946), see Fig. 7.7(b)

$$\text{Form 1. } \frac{\alpha}{1 - \lambda^4 \frac{\alpha}{3k^*}} = \frac{C(\lambda)}{\lambda B(\lambda)} \quad (7.6)$$

$$\text{Form 2. } \frac{\alpha}{1 - \lambda^4 \frac{\alpha}{3k^*}} = \frac{2 \cos \lambda \cosh \lambda}{\lambda (\sin \lambda \cosh \lambda - \sinh \lambda \cos \lambda)} \quad (7.6a)$$

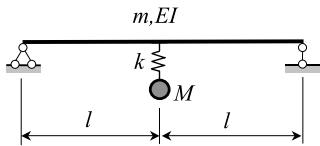

FIGURE 7.7(a). Design diagram.

where the dimensionless mass and stiffness parameters are

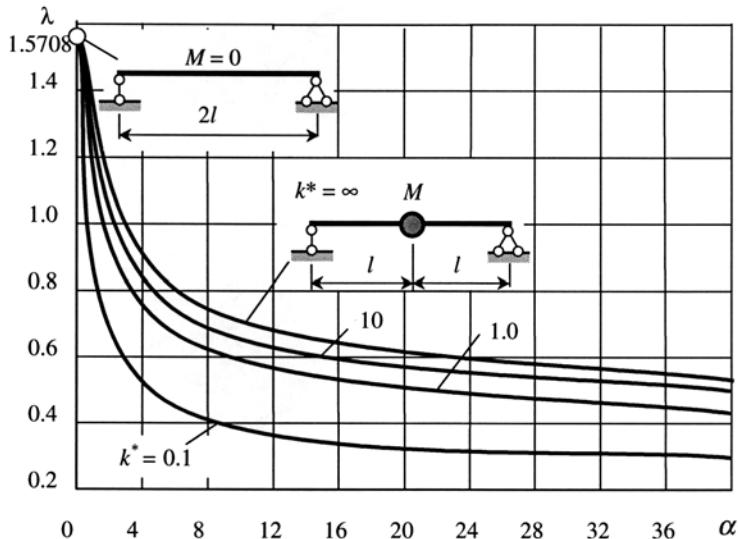

FIGURE 7.7(b). Simply supported beam with a spring mass at the middle of the span. Fundamental mode of vibration. Frequency parameter λ is a function of mass ratio $\alpha = M/2ml$ and stiffness ratio $k^* = kl^3/6EI$.

$$\alpha = \frac{M}{2ml} \quad k^* = \frac{kl^3}{6EI}$$

7.1.5 Beam with equal lumped masses on elastic supports

The design diagram of a symmetrical uniform beam with lumped masses on elastic supports is presented in Fig. 7.8.

The natural frequencies of vibration are

$$\omega_i = \frac{\lambda_i^2}{l_1^2} \sqrt{\frac{EI}{m}}$$

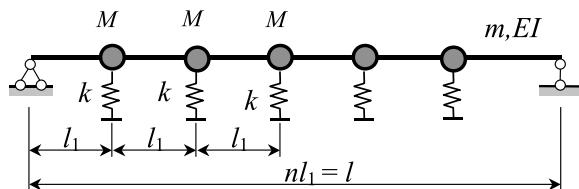

FIGURE 7.8. Design diagram.

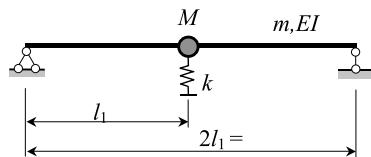

FIGURE 7.9. Design diagram.

where λ are roots of the frequency equation, which may be written in the form (Filippov, 1970)

$$\frac{\cos^2 \frac{v\pi}{n} - (\cosh \lambda + \cos \lambda) \cos \frac{v\pi}{n} + \cosh \lambda \cos \lambda}{\frac{\lambda}{2} [\cosh \lambda \sin \lambda - \sinh \lambda \cos \lambda + (\sinh \lambda - \sin \lambda) \cos \frac{v\pi}{n}]} = \frac{M}{2ml_1} - \frac{1}{\lambda^4} \frac{k l_1^3}{2EI} \quad (7.7)$$

where n is the number of segments and $v = 1, 2, 3, \dots$ are integers.

The relationship between the number of segments, n and the number, i , of the frequency of vibration is presented in Table 7.2.

TABLE 7.3. Simply supported uniform beam with one lumped mass on elastic support at the middle of the span: Fundamental frequency parameter λ for symmetrical vibration

α		k^*									
		0.0	1.0	2.0	4.0	6.0	8.0	10.0	15.0	20.0	40.0
	1.571	1.192	1.048	0.904	0.825	0.771	0.731	0.663	0.619	0.522	0.472
5.0	1.822	1.386	1.219	1.052	0.960	0.897	0.851	0.772	0.720	0.607	0.549
10.0	1.995	1.522	1.339	1.156	1.054	0.985	0.935	0.848	0.791	0.667	0.603
25.0	2.332	1.794	1.579	1.363	1.243	1.162	1.103	1.000	0.933	0.787	0.711
50.0	2.662	2.076	1.830	1.580	1.441	1.348	1.278	1.160	1.081	0.912	0.825

200	3.37	2.839	2.523	2.186	1.995	1.866	1.770	1.606	1.497	1.263	1.142
400	3.623	3.286	2.968	2.585	2.362	2.210	2.096	1.902	1.774	1.496	1.353

(1) First row (Case $\alpha = 0$) corresponds to the simply supported beam with the elastic support at the middle of the span.

(2) First column (Case $k = 0$) corresponds to the simply supported beam with the lumped mass at the middle of the span (see Equation (7.5)).

Special case. Let $l_1 = 0.5l$ (Fig. 7.9).

The number of segments $n = 2$ and frequency equation for $i = 1$ (fundamental frequency of vibration) becomes

$$\frac{2}{\lambda} \frac{\cosh \lambda \cos \lambda}{\cosh \lambda \sinh \lambda - \sinh \lambda \cos \lambda} = \frac{M}{2ml_1} - \frac{1}{2\lambda^4} \frac{kl_1^3}{EI} \quad (7.8)$$

Parameters λ_1 as a function of $k^* = \frac{kl_1^3}{EI}$ and $\alpha = \frac{M}{ml}$ are listed in Table 7.3.

7.2 BEAMS WITH OVERHANGS

7.2.1 Beam with one overhang and a lumped mass at the end

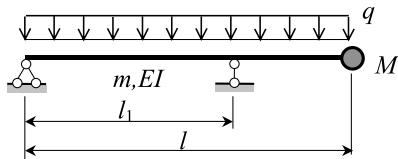

FIGURE 7.10. Design diagram.

The design diagram is presented in Fig. 7.10.

The natural frequency of vibration is

$$\omega = \frac{\lambda_1^2}{l_1^2} \sqrt{\frac{EI}{m_1}} = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m_1}}$$

where λ is a root of the following frequency equation (Filippov, 1970)

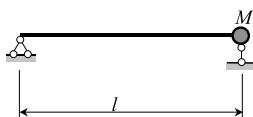

$$\begin{aligned} & (\cosh \lambda \xi \sin \lambda \xi - \sinh \lambda \xi \cos \lambda \xi)(\cosh \lambda \eta \sin \lambda \eta - \sinh \lambda \eta \cos \lambda \eta) \\ & - 2 \sinh \lambda \xi \sin \lambda \xi (1 + \cos \lambda \eta \cosh \lambda \eta) \\ & + 2 \frac{M}{m_1 l} \lambda [(\cosh \lambda \xi \sin \lambda \xi - \sinh \lambda \xi \cos \lambda \xi) \sin \lambda \eta \sinh \lambda \eta \\ & + \sinh \lambda \xi \sin \lambda \xi (\cosh \lambda \eta \sin \lambda \eta - \sinh \lambda \eta \cos \lambda \eta)] = 0 \end{aligned} \quad (7.9)$$

Here, dimensionless parameters are

$$\begin{aligned} \xi &= \frac{l_1}{l}; \quad \eta = 1 - \xi \\ m_1 &= m(1 + e), \quad e = \frac{q}{gm} \end{aligned}$$

Special cases

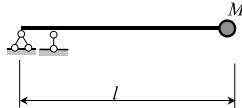

1. Pinned-pinned beam. In this case $\xi = 1$, and $\eta = 0$.

The frequency equation is

$$\sinh \lambda \sin \lambda = 0 \quad (\text{see Table 5.3})$$

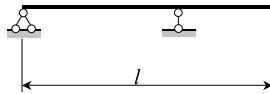

2. Clamped beam with a lumped mass at the end. In this case $\xi = 0$, and $\eta = 1$.

The frequency equation is

$$1 + \cos \lambda \cosh \lambda - \frac{M}{m_1 l} (\sin \lambda \cosh \lambda - \cos \lambda \sinh \lambda) = 0 \quad (\text{see Table 7.6}).$$

3. Beam with one overhang ($M = 0$) (Morrow, 1908; Chree, 1914) (see Section 5.2).

The frequency equation is

$$(\cosh \lambda \xi \sin \lambda \xi - \sinh \lambda \xi \cos \lambda \xi)(\cosh \lambda \eta \sin \lambda \eta - \sinh \lambda \eta \cos \lambda \eta) - 2 \sinh \lambda \xi \sin \lambda \xi (1 + \cos \lambda \eta \cosh \lambda \eta) = 0$$

7.2.2 Beam with two overhangs and lumped masses at the ends

The design diagram is presented in Fig. 7.11(a). The natural frequency of vibration is given by $\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$, where λ is the root of the frequency equation.

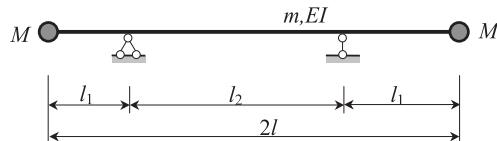

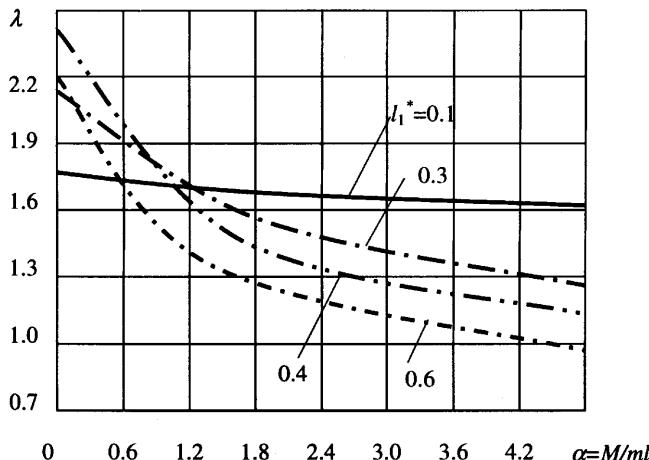

Symmetrical vibration. The frequency equation in terms of Hohenemser-Prager's functions (Anan'ev, 1946) is

$$\frac{M}{ml} = \frac{1}{\lambda} \frac{C[\lambda(1 - l_1^*)]E(\lambda l_1^*) - A[\lambda(1 - l_1^*)]B(\lambda l_1^*)}{C[\lambda(1 - l_1^*)]B(\lambda l_1^*) + A[\lambda(1 - l_1^*)]S_1(\lambda l_1^*)} \quad (7.10)$$

where the dimensionless parameters are

$$l_1^* = \frac{l_1}{l}, \quad l_2^* = \frac{l_2}{2l}, \quad l = l_1 + \frac{l_2}{2}, \quad \alpha = \frac{M}{ml}$$

The frequency parameters λ as a function of mass ratio $\alpha = M/ml$ and parameter $l_1^* = l_1/l$ for the fundamental mode of vibration are shown in Fig. 7.11(b).

**FIGURE 7.11(a).** Design diagram.**FIGURE 7.11(b).** Beam with two overhangs and lumped masses at the ends. Fundamental mode of vibration. Frequency parameter \$\lambda\$ as a function of mass ratio \$\alpha = M/ml\$ and geometry ratio \$l_1^* = l_1/l\$.

Antisymmetric vibration. The frequency equation may be presented in the form

$$\frac{M}{ml} = \frac{1}{\lambda B[\lambda(1 - l_1^*)]} \frac{S_1[\lambda(1 - l_1^*)]E(\lambda l_1^*) - B[\lambda(1 - l_1^*)]B(\lambda l_1^*)}{S_1[\lambda(1 - l_1^*)] - S_1(\lambda l_1^*)} \quad (7.11)$$

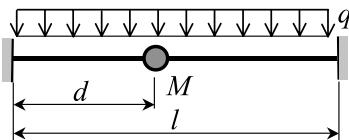

Example. Derive the frequency equation for the symmetrical vibration of a three-span beam with pinned supports at both ends.

Solution. This case corresponds to a simply-supported beam with two overhangs and two infinite lumped masses at the ends (\$M = \infty\$). The frequency equation is

$$C[\lambda(1 - l_1^*)]B(\lambda l_1^*) + C[\lambda(1 - l_1^*)]S_1(\lambda l_1^*) = 0$$

7.3 CLAMPED BEAM WITH A LUMPED MASS ALONG THE SPAN

Figure 7.12(a) shows a fixed-fixed beam with a uniformly distributed load \$q\$ and a concentrated mass at an arbitrary location \$d\$ from the left support.

(a)

FIGURE 7.12(a). Design diagram.

The natural frequency of vibration of the beam is $\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m(1+e)}}$, $e = \frac{q}{g\rho A}$. The frequency parameters λ are roots of the following frequency equation (Filippov, 1970).

$$\begin{vmatrix} U(1) + \alpha\lambda^4 U(\xi_1)V(\xi_2) & V(1) + \alpha\lambda^4 V(\xi_1)V(\xi_2) \\ U'(1) + \alpha\lambda^4 U(\xi_1)V'(\xi_2) & V'(1) + \alpha\lambda^4 V(\xi_1)V'(\xi_2) \end{vmatrix} = 0 \quad (7.12)$$

where Krylov-Duncan functions and dimensionless parameters are

$$\begin{aligned} U(\xi) &= \frac{1}{2\lambda^2} (\cosh \lambda \xi - \cos \lambda \xi) \\ V(\xi) &= \frac{1}{2\lambda^3} (\sinh \lambda \xi - \sin \lambda \xi) \\ \xi_1 &= \frac{d}{l}; \quad \xi_2 = 1 - \xi_1; \quad \xi = \frac{x}{l}; \quad \alpha = \frac{M}{(1+e)ml} \end{aligned}$$

The frequency parameter λ as a function of mass ratio α and the parameter ξ_1 for the fundamental mode of vibration are shown in Fig. 7.12(b) (Morrow, 1906; Pfeiffer, 1928).

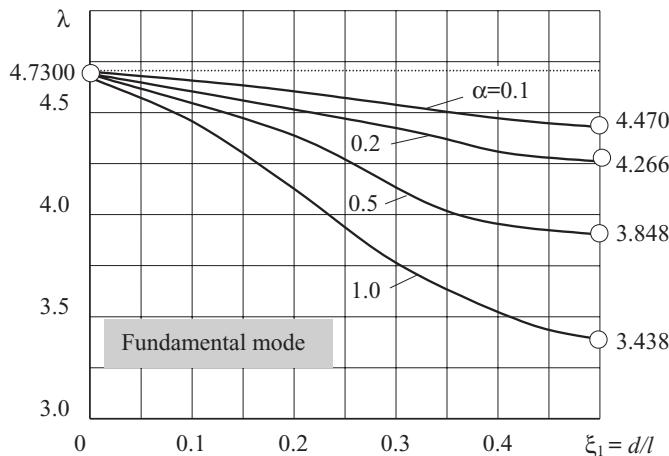

FIGURE 7.12(b). Clamped beam with a lumped mass along the span. Fundamental mode of vibration. Frequency parameter λ as a function of mass ratio $\alpha = M/ml$ and geometry ratio $l_1^* = l_1/l$.

Special case. Let $d = 0.5l$. The frequency equation is $D_1 D_2 = 0$, where

$$D_1 = \left(\sin \frac{\lambda}{2} \cosh \frac{\lambda}{2} - \cos \frac{\lambda}{2} \sinh \frac{\lambda}{2} \right)$$

$$D_2 = \left[\cosh \frac{\lambda}{2} \sin \frac{\lambda}{2} + \sinh \frac{\lambda}{2} \cos \frac{\lambda}{2} + \frac{\alpha \lambda}{2} \left(\cosh \frac{\lambda}{2} \cos \frac{\lambda}{2} - 1 \right) \right]$$

Antisymmetric vibration (AsV). The frequency equation is $D_1 = 0$. In this case, point $\xi = 0.5$ is the nodal point. In terms of Hohenemser-Prager functions, a frequency equation and frequency parameter are

$$D_1 = B(0.5\lambda) = 0 \rightarrow 0.5\lambda_{\min} = 3.92651$$

So, the equation $D_1 = B(0.5\lambda) = 0$ corresponds to clamped-pinned beam of length $0.5l$ and mass M attached on the axis of symmetry. In this case, it is possible to assume that $M = 0$.

Symmetrical vibration (SV). The frequency equation is $D_2 = 0$. Parameter λ_1 of the fundamental frequency vibration (first mode of symmetric vibration) can be taken from Table 7.4(a).

Parameter λ_3 of the third frequency of vibration (second mode of symmetric vibration) is listed in Table 7.4(b).

TABLE 7.4(a). Clamped uniform beam with lumped mass at the middle of the span: Fundamental frequency parameter λ for symmetric vibration

α	0.0	0.05	0.10	0.15	0.20	0.25	0.50	0.75	1.0	1.5

α	2.0	4.0	6.0	8.0	10.0	15.0	20.0	25.0	30.0	∞
λ	3.000	2.574	2.342	2.188	2.074	1.880	1.752	1.658	1.586	0.0

TABLE 7.4(b). Clamped uniform beam with lumped mass at the middle of the span: Frequency parameter for second mode of symmetric vibration

α	0.00	0.10	0.50	1.0	10.0	20.0	40.0	∞
λ	10.996	10.588	10.000	9.786	9.500	9.480	9.470	9.46

The first mode of antisymmetric vibration: $\lambda_2 = 7.8532$ (see Table 5.3).

Symmetric vibration has a band frequency spectrum, while antisymmetric vibration has a discrete frequency spectrum (Fig. 7.13).

Expressions for the mode shape vibration are presented in Section 7.7.

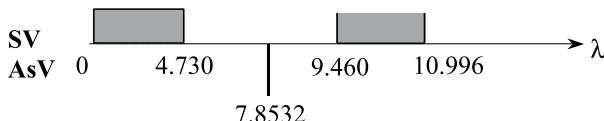

FIGURE 7.13. Frequency spectrum.

7.4 FREE-FREE BEAMS

7.4.1 Beam with a lumped mass at the middle of the span

Figure 7.14(a) shows a free-free beam with concentrated mass at the middle of the span.

The natural frequency of vibration is $\omega = \frac{\lambda^2}{l_2} \sqrt{\frac{EI}{m}}$. The frequency parameters λ are the roots of the frequency equation.

Symmetrical vibration. The frequency equation may be presented as follows.

$$\begin{aligned} \text{Form 1. } \frac{M}{2ml} &= -\frac{1}{\lambda} \frac{A(\lambda)}{E(\lambda)} \\ \text{Form 2. } \frac{M}{2ml} &= -\frac{1}{\lambda} \frac{S(\lambda)T(\lambda) - U(\lambda)V(\lambda)}{S^2(\lambda) - T(\lambda)V(\lambda)} \\ \text{Form 3. } \frac{M}{2ml} &= -\frac{1}{\lambda} \frac{\cosh \lambda \sin \lambda + \sinh \lambda \cos \lambda}{\cosh \lambda \cos \lambda + 1} \end{aligned} \quad (7.13)$$

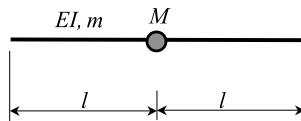

FIGURE 7.14(a). Design diagram.

Symmetrical vibration

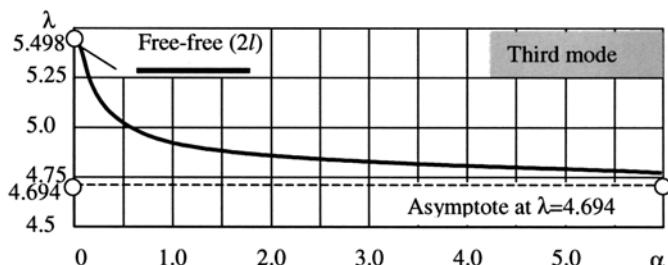

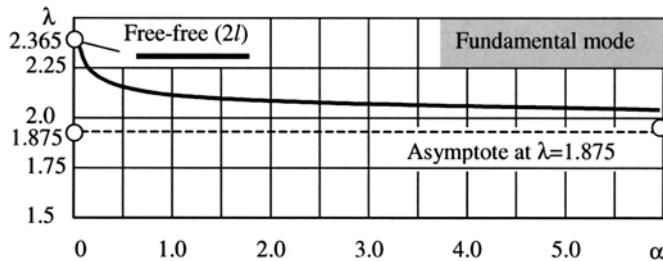

FIGURE 7.14(b). Free-free beam with a lumped mass at the middle of the span. Fundamental and third mode of vibration. Frequency parameter λ as a function of mass ratio $\alpha = M/ml$.

Frequency parameters λ , as a function of the mass ratio $\alpha = M/2ml$ for symmetrical modes of vibration (fundamental and third mode of vibration) are shown in Fig. 7.14(b) (Anan'ev, 1946).

Antisymmetric vibration. The frequency equation may be presented in a different form, as follows

- Form 1. $B(\lambda) = 0$
- Form 2. $T(\lambda)U(\lambda) - S(\lambda)V(\lambda) = 0$ (7.14)
- Form 3. $\cosh \lambda \sin \lambda - \sinh \lambda \cos \lambda = 0$

The roots of the frequency equation are

$$\lambda_1 = 3.92651; \quad \lambda_2 = 7.06848$$

The symmetric vibration has a band frequency spectrum and the antisymmetric vibration has a discrete frequency spectrum (Fig. 7.15).

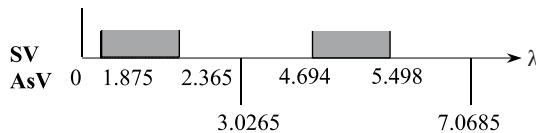

FIGURE 7.15. Frequency spectrum.

The case $\lambda = 0$ corresponds to the vibration of the beam without bending deformation (vibration as a rigid body) (Table 5.3).

Example. Find the mass ratio parameter $\alpha = \frac{M}{2ml}$, which leads to frequency parameter $\lambda = 2.2$.

Solution. The frequency equation is

$$\frac{M}{2ml} = -\frac{1}{\lambda} \frac{A(\lambda)}{E(\lambda)}$$

$$\text{so parameter } \alpha = -\frac{1}{2.2} \frac{1.07013}{(-1.68822)} = 0.288.$$

7.4.2 Beam with a translational spring and a lumped mass at the middle of the span

Figure 7.16(a) shows a free-free beam carrying the lumped mass supported by one spring at the middle of the span.

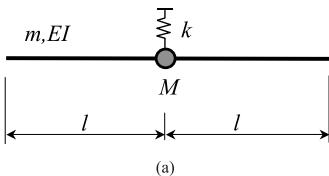

FIGURE 7.16(a). Design diagram.

The natural frequencies of vibration are

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$$

The frequency parameter λ is the root of the frequency equation.

Symmetrical vibration. The frequency equation may be presented as follows

$$\begin{aligned} \text{Form 1. } k^* - \alpha \lambda^4 &= \lambda^3 \frac{A(\lambda)}{E(\lambda)} \\ \text{Form 2. } k^* - \alpha \lambda^4 &= \lambda^3 \frac{S(\lambda)T(\lambda) - U(\lambda)V(\lambda)}{S^2(\lambda) - T(\lambda)V(\lambda)} \\ \text{Form 3. } k^* - \alpha \lambda^4 &= \lambda^3 \frac{\cosh \lambda \sin \lambda + \sinh \lambda \cos \lambda}{\cosh \lambda \cos \lambda + 1} \end{aligned} \quad (7.15)$$

where dimensionless parameters are

$$k^* = \frac{kl^3}{2EI} \quad \alpha = \frac{M}{2ml}$$

Frequency parameters λ as a function of mass ratio $\alpha = M/2ml$ and stiffness ratio $k^* = kl^3/2EI$ for the fundamental and third modes of vibration are shown in Fig. 7.16(b) (Anan'ev, 1946).

Special cases for symmetrical vibration are presented in Table 7.5.

TABLE 7.5. Free-ended uniform beam with translational spring and lumped mass at the middle of the span: Frequency equations

Design diagram	Parameter	Frequency equation	Related formulas
	$k = 0$	$\alpha = -\frac{1}{\lambda} \frac{A(\lambda)}{E(\lambda)}$	Section 7.4
	$M = 0$	$k^* = \lambda^3 \frac{A(\lambda)}{E(\lambda)}$	Section 6.7

Antisymmetric vibration. The frequency equation may be presented as follows:

$$\begin{aligned} \text{Form 1. } B(\lambda) &= 0 \\ \text{Form 2. } T(\lambda)U(\lambda) - S(\lambda)V(\lambda) &= 0 \\ \text{Form 3. } \cosh \lambda \sin \lambda - \sinh \lambda \cos \lambda &= 0 \end{aligned} \quad (7.16)$$

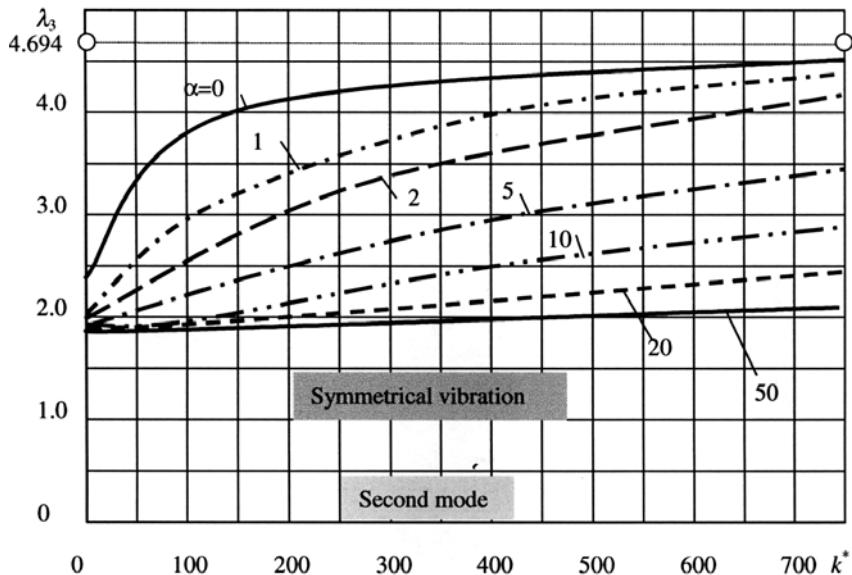

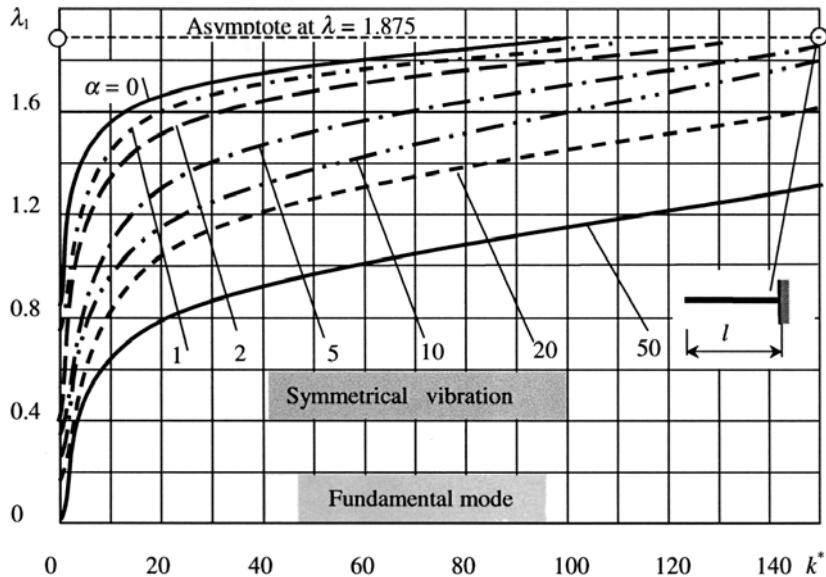

FIGURE 7.16(b). Free-free beam supported by a spring with a lumped mass at the middle of the span. Symmetrical vibration. Frequency parameter λ as a function of mass ratio $\alpha = M/ml$ and stiffness ratio $k^* = kl^3/2EI$.

The frequency parameters are $\lambda_1 = 3.926$, $\lambda_2 = 7.0685$.

The symmetrical vibration has a band frequency spectrum and the antisymmetric vibration has a discrete frequency spectrum (Fig. 7.17).

FIGURE 7.17. Frequency spectrum.

Example. Calculate the dimensionless stiffness parameter k^* which, together with mass ratio $\alpha = 5.0$, leads to the frequency parameter $\lambda = 1.6$.

Solution. Stiffness parameter

$$k^* = \alpha \lambda^4 + \lambda^3 \frac{A(\lambda)}{E(\lambda)} = 5.0 \times 1.6^4 + 1.6^3 \frac{2.5070}{0.92474} = 43.872$$

Example. For a free-free beam of length $2l$, the parameters m , l and EI are known. Is it possible to find parameters for a translational spring and a lumped mass at the middle of the span which leads to the eigenvalue $\lambda = 2.2$?

Solution. From the frequency spectrum graph we can see that parameter $\lambda = 2.2$ cannot be realized.

7.5 BEAMS WITH DIFFERENT BOUNDARY CONDITIONS AT ONE END AND A LUMPED MASS AT THE FREE END

A beam with typical boundary conditions at the left-hand end and a lumped mass at the right-hand end is shown in Fig. 7.18.

Dimensionless parameters are

$$\alpha = \frac{M}{ml}, \quad \xi = \frac{x}{l}, \quad 0 \leq \xi \leq 1$$

The frequency of vibration is equal to

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}, \quad m = \rho A$$

FIGURE 7.18. Design diagram of a beam; the left-hand end of the beam is free, or pinned or clamped.

where λ is a root of the frequency equation. The exact solution of the eigenvalue and eigenfunction problem (frequency equation and mode shape vibration) for beams with classical boundary condition at the left-hand end and a lumped mass at right-hand end are presented in Table 7.6 (Anan'ev, 1946; Gorman, 1975).

TABLE 7.6. Eigenvalues and eigenfunction for beams with different boundary conditions (left-hand end) with a lumped mass at the free end

Left end	Frequency equation	Mode shape $X(\xi)$	Parameter γ
Free	$\frac{1}{\alpha} = \lambda \frac{\sinh \lambda \cos \lambda - \cosh \lambda \sin \lambda}{1 - \cos \lambda \cosh \lambda}$	$\sin \lambda \xi + \sinh \lambda \xi + \gamma(\cos \lambda \xi + \cosh \lambda \xi)$	$\frac{\sin \lambda - \sinh \lambda}{\cosh \lambda - \cos \lambda}$
Pinned	$\frac{1}{\alpha} = \lambda \frac{2 \sin \lambda \sinh \lambda}{\cos \lambda \sinh \lambda - \sin \lambda \cosh \lambda}$	$\sin \lambda \xi + \gamma \sinh \lambda \xi$	$\frac{\sin \lambda}{\sinh \lambda}$
Clamped	$\frac{1}{\alpha} = \lambda \frac{\sin \lambda \cosh \lambda - \sinh \lambda \cos \lambda}{1 + \cos \lambda \cosh \lambda}$	$\sinh \lambda \xi - \sin \lambda \xi + \gamma(\cosh \lambda \xi - \cos \lambda \xi)$	$-\frac{\sin \lambda + \sinh \lambda}{\cos \lambda + \cosh \lambda}$

Special cases. (Related formulas are presented in Table 5.3).

If $M = 0$, then the frequency equations for a beam with different boundary conditions are:

$$\text{Free-free beam: } 1 - \cos \lambda \cosh \lambda = 0$$

$$\text{Pinned-free beam: } \cos \lambda \sinh \lambda - \sin \lambda \cosh \lambda = 0$$

$$\text{Clamped-free beam: } 1 + \cos \lambda \cosh \lambda = 0$$

If $M = \infty$, then the impedance of the mass is equal to infinity, which corresponds to a pinned beam supported at the right-hand end, so the frequency equations for a beam with different boundary conditions become:

$$\text{Free-pinned beam: } \sinh \lambda \cos \lambda - \cosh \lambda \sin \lambda = 0$$

$$\text{Pinned-pinned beam: } \sin \lambda = 0$$

$$\text{Clamped-pinned beam: } \sin \lambda \cosh \lambda - \sinh \lambda \cos \lambda = 0$$

NUMERICAL RESULTS

7.5.1 Cantilever beam with a lumped mass at the end

Frequency parameter λ_1 , the fundamental frequency of vibration, and λ_2 , the second frequency of vibration, as a function of mass ratio $\alpha = M/ml$, are listed in Tables 7.7(a) and 7.7(b), respectively. Bold data correspond to the limiting cases.

Frequency parameters λ_1 and λ_2 as a function of mass ratio $\alpha = M/ml$ for fundamental and second modes of vibration are shown in Fig. 7.19 (Anan'ev, 1946).

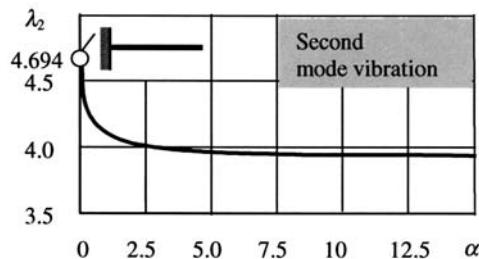

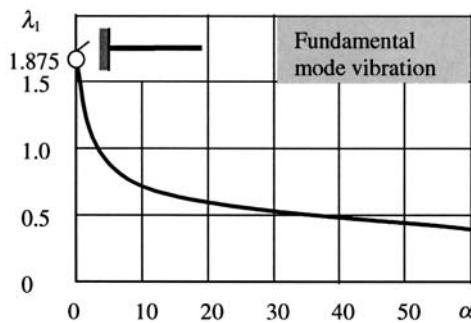

The vibration has band frequency spectrum with mixed numbers of shape modes (Fig. 7.20). Point $\lambda = 0.00$ corresponds to clamped-free beam with $M = \infty$. It means that the beam does not vibrate. Point $\lambda = 1.875$ corresponds to a fundamental mode of the clamped-free beam without M . Points $\lambda = 3.926$ and $\lambda = 4.6941$ correspond to the

fundamental modes of vibration of a clamped–pinned beam and the second mode of vibration of a clamped–free beam without M , respectively.

Example. Consider a clamped–free beam carrying a lumped mass M at the free end, $\alpha = M/ml = 0.5$. Calculate the eigenvalue and eigenfunctions that correspond to the fundamental mode of vibration.

Solution. From Table 7.7, the frequency parameter $\lambda = 1.420$.

Parameter γ according to Table 7.6 is

$$\gamma = -\frac{\sin \lambda + \sinh \lambda}{\cos \lambda + \cosh \lambda} = -\frac{0.98865 + 1.94770}{0.15023 + 2.18942} = -1.255038$$

Mode shape of vibration

$$X(\xi) = \sinh 1.420\xi - \sin 1.420\xi - 1.255038(\cosh 1.420\xi - \cos 1.420\xi)$$

Nodal point at $\xi = 0.0$.

The maximum velocity of the free end

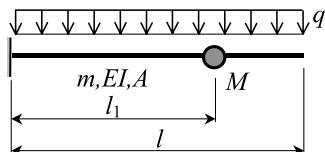

$$\begin{aligned}|v_{\max}| &= \lambda X(1) = 1.420 \times [1.94770 - 0.98865 - 1.255038(2.18942 - 0.15023)] \\ &= 2.2723\end{aligned}$$

7.5.2 Cantilever beam with a lumped mass along the span

Figure 7.21(a) shows a clamped–free beam carrying the uniformly distributed load and one lumped mass along the span.

Natural frequencies of vibration are

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m(1+e)}}, \quad m = \rho A$$

**FIGURE 7.21(a).** Design diagram.

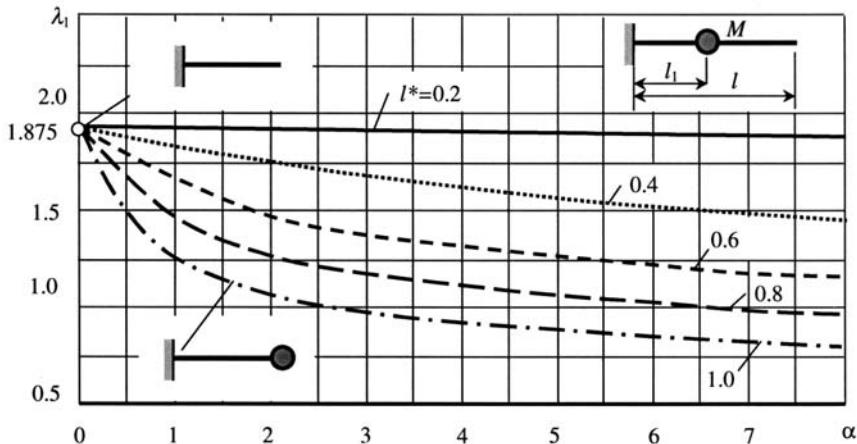

FIGURE 7.21(b). Cantilever beam with a lumped mass along the span. Fundamental mode of vibration. Frequency parameter λ_1 as a function of mass ratio $\alpha = M/ml$ and spacing $l^* = l_1/l$.

The frequency parameters λ are the roots of the frequency equation, which may be presented in terms of Krylov-Duncan functions (Filippov, 1970)

$$\begin{aligned} S^2(\lambda) - T(\lambda)V(\lambda) + \lambda n S[\lambda(1 - l^*)] &\{S(\lambda)V(\lambda l^*) - T(\lambda)U(\lambda l^*)\} + \lambda n T[\lambda(1 - l^*)] \\ &\times \{S(\lambda)U(\lambda l^*) - V(\lambda)V(\lambda l^*)\} = 0 \end{aligned} \quad (7.17)$$

where dimensionless parameters are

$$n = \frac{M}{(1+e)ml}; \quad e = \frac{q}{g\rho A}; \quad l^* = \frac{l_1}{l}$$

Frequency parameters λ as a function of mass ratio $\alpha = M/ml$ and mass position ratio $l^* = l_1/l$ for the fundamental mode of vibration, is shown in Fig. 7.21(b) (Anan'ev, 1946).

The beam has a band frequency spectrum, which is presented in Fig. 7.21(c).

FIGURE 7.21(c). Clamped-free beam with a lumped mass along the span. Frequency spectrum.

Special cases

1. If $M = 0$ or $l^* = 0$ (cantilever beam), then the frequency equation is

$$1 + \cos \lambda \cosh \lambda = 0 \quad (\text{see Table 5.3})$$

2. If $l^* = 1$ (cantilever beam with lumped mass at the free end), then the frequency equation is

$$1 + \cos \lambda \cosh \lambda - n\lambda(\sin \lambda \cosh \lambda - \cos \lambda \sinh \lambda) = 0$$

(see Sections 7.2 and 7.5.3; Table 7.6).

7.5.3 Elastic cantilever beam with a lumped mass at the free end

Figure 7.22(a) shows a pinned-free beam carrying the lumped mass at the free end. A rotational spring is attached at the pinned support of the beam. The restoring moment, which arises in this spring, is $M = k_r \frac{\partial y}{\partial x}$.

The natural frequency of vibration is

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}, \quad m = \rho A$$

Frequency parameters λ are the roots of a frequency equation, which may be presented in terms of Hohenemser-Prager functions (Anan'ev, 1946; Filippov, 1970)

$$\frac{M}{ml} = \frac{\frac{k^*}{\lambda} E(\lambda) - B(\lambda)}{\lambda S_1(\lambda) + k^* B(\lambda)} \quad (7.18)$$

where the dimensionless parameters are

$$n = \frac{M}{ml} \quad k^* = \frac{k_r l}{EI}$$

For a fundamental mode of vibration frequency, parameters λ , as a function of mass ratio and stiffness ratio, are shown in Fig. 7.22(b) (Anan'ev, 1946). For $k^* = 0$, frequency parameter $\lambda = 0$. This case is presented by a horizontal line, which coincides with the α -axis. It means that the beam rotates around pinned support as a solid body without any bending deformation.

Frequency equations for special cases

1. Pinned-free beam with a lumped mass at the free end ($k_{\text{rot}} = 0$)

$$\frac{M}{ml} = -\frac{B(\lambda)}{\lambda S_1(\lambda)} \rightarrow \frac{M}{ml} = -\frac{\cosh \lambda \sin \lambda - \sinh \lambda \cos \lambda}{2\lambda \sin \lambda \sinh \lambda} \quad (\text{see Table 7.6})$$

2. Elastic cantilever beam ($M = 0$)

$$k^* E(\lambda) - \lambda B(\lambda) = 0 \rightarrow k^* - \lambda \frac{\cosh \lambda \sin \lambda - \sinh \lambda \cos \lambda}{1 + \cosh \lambda \sin \lambda} = 0 \quad (\text{see Table 6.11})$$

3. Clamped-free beam ($k_{\text{rot}} = \infty$, and $M = 0$)

$$E(\lambda) = 0 \rightarrow 1 + \cosh \lambda \sin \lambda = 0 \quad (\text{see Table 5.3})$$

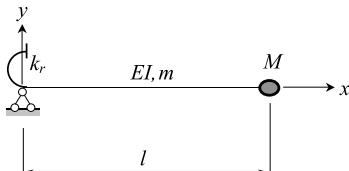

FIGURE 7.22(a). Design diagram.

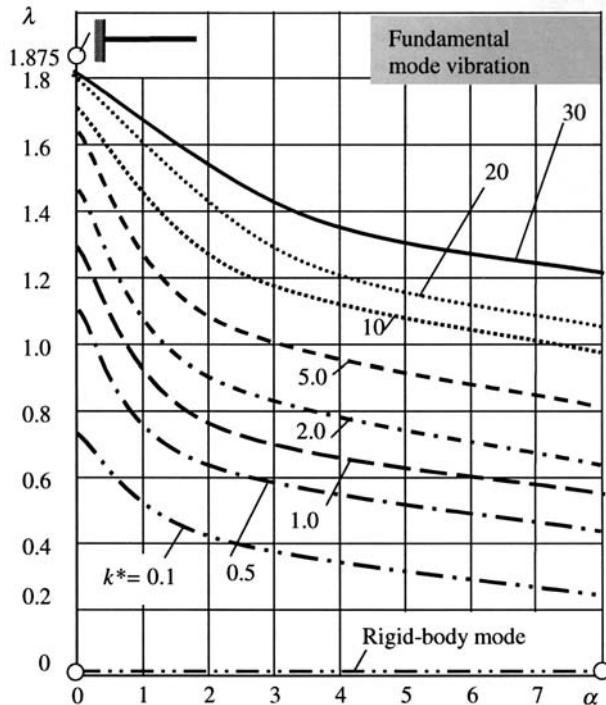

FIGURE 7.22(b). Pinned-free beam with a rotational spring at the pinned end and a lumped mass at the free end. Fundamental mode of vibration. Frequency parameter λ as a function of mass ratio $\alpha = M/ml$ and stiffness ratio $k^* = kl/EI$.

4. Clamped-free beam with a lumped mass at the free end ($k_{\text{rot}} = \infty$)

$$\frac{M}{ml} = \frac{E(\lambda)}{\lambda B(\lambda)} \rightarrow \frac{ml}{M} = \lambda \frac{\cosh \lambda \sin \lambda - \sinh \lambda \cos \lambda}{1 + \cosh \lambda \sin \lambda} \quad (\text{see Section 7.5.2})$$

5. Pinned-free beam ($k_{\text{rot}} = 0$, and $M = 0$)

$$B(\lambda) = 0 \rightarrow \cosh \lambda \sin \lambda - \sinh \lambda \cos \lambda = 0 \quad (\text{see Table 5.3}).$$

7.5.4 Beam with a sliding-spring support at one end and a lumped mass at the other

Figure 7.23(a) shows a beam with the sliding-spring support at the left-hand end and free at right-hand end. The beam is carrying the lumped mass at the free end; the restoring force, which arises in the translational spring, is $R = ky$.

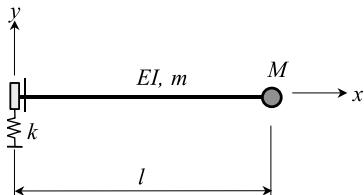

FIGURE 7.23(a). Design diagram.

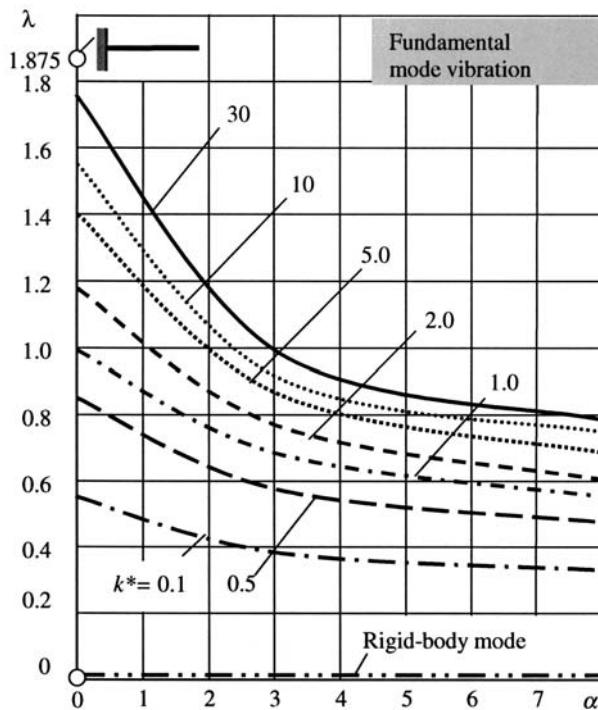

FIGURE 7.23(b). Elastic cantilever beam with a lumped mass at the free end. Fundamental mode of vibration. Frequency parameter λ as a function of mass ratio $\alpha = M/ml$ and stiffness ratio $k^* = kl^3/EI$.

The natural frequency of vibration is

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}, \quad m = \rho A$$

The frequency parameters λ are the roots of the frequency equation, which may be presented in terms of Hohenemser–Prager functions (Anan'ev, 1946)

$$\frac{M}{ml} = \frac{\frac{k^*}{\lambda^3} E(\lambda) - A(\lambda)}{\lambda C(\lambda) + \frac{k^*}{\lambda^2} B(\lambda)} \quad (7.19)$$

where dimensionless parameters are

$$\alpha = \frac{M}{ml} \quad k^* = \frac{kl^3}{EI}$$

Eigenvalues λ as a function of mass ratio $\alpha = M/ml$ and stiffness ratio $k^*_{tr} = kl^3/EI$ for the fundamental mode of vibration are shown in Fig. 7.23(b). For $k^*_{tr} = 0$, frequency parameter $\lambda = 0$. This case is presented by the horizontal line, which coincides with the n -axis. It means that the beam is in translation as a solid body without any bending deformation.

Frequency equations for special cases

1. Sliding-free beam ($k = 0, M = 0$). The frequency equation is

$$A(\lambda) = 0 \rightarrow \tan \lambda + \tanh \lambda = 0 \quad (\text{see Table 5.4})$$

2. Cantilever beam with a lumped mass at the free end ($k = \infty$). The frequency equation is

$$\alpha = \frac{E(\lambda)}{\lambda B(\lambda)} \quad (\text{see Sections 7.5.2 and 7.5.3; Table 7.6})$$

7.5.5 Beam with a translational and torsional spring support at one end and a lumped mass at the other

Figure 7.24 shows a beam with non-classical boundary conditions—a translation and torsional spring support at the left-hand end and a lumped mass at the right-hand end. The restoring force and the restoring moment that arise in the translational and rotational springs are $R = k_{tr}y$ and $M = k_{rot} \frac{\partial y}{\partial x}$, respectively.

The natural frequency of vibration is

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$$

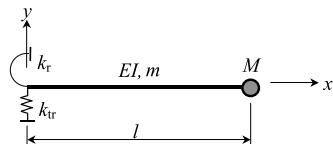

FIGURE 7.24. Beam with non-classical boundary conditions.

The frequency parameters λ are the roots of the frequency equation which may be written as (Anan'ev, 1946)

$$\frac{k_{\text{tr}}^*}{\lambda^3} [k_r^* E(\lambda) - \lambda B(\lambda) - n \lambda^2 S_1(\lambda) - nk_r^* \lambda B(\lambda)] - \lambda D(\lambda) + n \lambda^2 B(\lambda) - n \lambda k_r^* C(\lambda) - k_r^* A(\lambda) = 0 \quad (7.20)$$

where A , E , B , D and S_1 are Hohenemser-Prager functions.

The dimensionless parameters are

$$k_{\text{tr}}^* = \frac{k_{\text{tr}} l^3}{EI} \quad k_r^* = \frac{k_r l}{EI} \quad n = \frac{M}{ml}$$

Frequency equations for special cases.

1. If $M = 0$, $k_{\text{rot}} = 0$, then the frequency equation is

$$k_{\text{tr}}^* B(\lambda) = -\lambda^3 D(\lambda) \quad (\text{see Section 6.2.1})$$

2. If $M = 0$, $k_{\text{tr}} = 0$, then the frequency equation is

$$\lambda D(\lambda) + k_r^* A(\lambda) = 0 \quad (\text{see Table 6.6})$$

3. If $M = 0$, then the frequency equation is

$$\frac{k_{\text{tr}}^*}{\lambda^3} [k_r^* E(\lambda) - \lambda B(\lambda)] - \lambda D(\lambda) - k_r^* A(\lambda) = 0 \quad (\text{see Table 6.9})$$

7.6 BEAMS WITH DIFFERENT BOUNDARY CONDITIONS AND LUMPED MASSES

Figure 7.25 shows a beam with arbitrary boundary conditions and lumped masses along the span; the specific boundary conditions are not shown.

The lumped masses M_i are reduced to 'equivalent' distributed mass m . The value of this mass is defined by the mode shape X_i . The adjustment mass method is conveniently used for the cases of different masses that have different intervals between them.

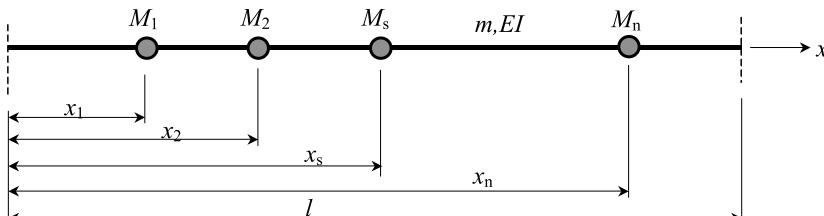

FIGURE 7.25. Design diagram of a beam with arbitrary boundary condition and different lumped masses.

7.6.1 Method adjustment mass

The natural frequencies of vibrations may be calculated by the approximate formula

$$\omega_i = \frac{\lambda_i^2}{l^2} \sqrt{\frac{EI}{m_i}} \quad (7.21)$$

In this method, the eigenvalues λ depend only boundary conditions and take the values as for uniform beams without lumped masses. Eigenvalues λ_i for one-span beams with different boundary conditions are given in Table 5.1. The adjustment uniform mass m_i corresponding to the i th eigenform is (Korenev, 1970)

$$m_i = m + \frac{1}{l} \sum_{s=1}^n X_i^2(\xi_s) M_s, \quad \xi_s = \frac{x_s}{l} \quad (7.22)$$

where expressions $X_i^2(\xi_s)$ are the adjustment coefficient of the s th mass to the uniform mass m . The normalized eigenfunctions $X_i(\xi_s)$ for one-span and multispan beams with different boundary conditions are given in Applications A and B.

It should be emphasized that the symmetry of the position of the lumped masses, the small difference between them as well as between masses and one of the beams, leads to a more accurate result.

Example. Determine the fundamental frequency of vibration of the cantilever beam with lumped mass at the free end, if the mass ratio $\alpha = M/ml = 0.5$.

Solution. The first eigenfunction at $\xi = x/l = 1$ is $X_1(1) = 2.0$. The adjustment of uniform mass m_1 corresponding to the first eigenform is

$$m_1 = m + \frac{1}{l} (2)^2 (0.5ml) = 3m$$

The fundamental frequency of vibration is

$$\omega_1 = \frac{\lambda_1^2}{l^2} \sqrt{\frac{EI}{m_1}} = \frac{1.875^2}{l^2} \sqrt{\frac{EI}{3m}} = \frac{1.4246^2}{l^2} \sqrt{\frac{EI}{m}}$$

The accuracy value is $\lambda = 1.4200$, the error is $+1\%$.

Example. Determine the first and second frequencies of vibration of the pinned-clamped beam with lumped masses located as shown in Fig. 7.26. Let $M_1 = 0.2ml$; $M_2 = 0.25ml$; $M_3 = 0.3ml$; $M_4 = 0.25ml$. The x -coordinates of the masses are $x_1 = 0.2l$; $x_2 = 0.3l$; $x_3 = 0.5l$; $x_4 = 0.8l$.

Solution. For the pinned-clamped beam, the exact frequency parameters are $\lambda_1 = 3.927$; $\lambda_2 = 7.069$ (Table 5.3).

For a beam with the given boundary conditions, the ordinates X_1 and X_2 for the specified x_s are taken from Appendix A and presented in Table 7.8.

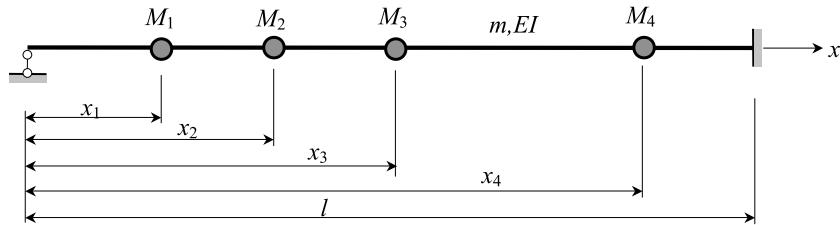

FIGURE 7.26. Design diagram of a beam with lumped masses.

TABLE 7.8 Ordinates of first and second eigenvalues at $x = x_i$

x_i	0.2l	0.3l	0.5l	0.8l
X_1	1.0346	1.365	1.4449	0.4557
X_2	1.3935	1.1988	-0.5703	-1.0774

Adjustment of the uniform masses, corresponding to the first and second eigenforms are

$$\begin{aligned} m_1 &= m + \frac{1}{l} \sum_{k=1}^4 X_1^2(\alpha_k) M_k = m + \frac{1}{l} [1.0346^2 \times 0.2 + 1.365^2 \\ &\quad \times 0.25 + 1.4449^2 \times 0.3 + 0.4557^2 \times 0.25] ml; \quad m_1 = 2.3581m \\ m_2 &= m + \frac{1}{l} \sum_{k=1}^4 X_2^2(\alpha_k) M_k = m + \frac{1}{l} [1.3935^2 \times 0.2 + 1.1988^2 \\ &\quad \times 0.25 + (-0.5703)^2 \times 0.3 + (-1.0774)^2 \times 0.25] ml; \quad m_2 = 2.1354m \end{aligned}$$

The fundamental and second frequencies of vibration are

$$\begin{aligned} \omega_1 &= \frac{\lambda_1^2}{l^2} \sqrt{\frac{EI}{m_1}} = \frac{3.927^2}{l^2} \sqrt{\frac{EI}{2.3581m}} \\ \omega_2 &= \frac{\lambda_2^2}{l^2} \sqrt{\frac{EI}{m_2}} = \frac{7.069^2}{l^2} \sqrt{\frac{EI}{2.1354m}} \end{aligned}$$

Example. Calculate the fundamental frequency of vibration for a cantilever beam with the attached body having mass M and moment of inertia J (Fig. 7.27). The location parameter is $x_1/l = 0.6$ from the free end.

Assume that $\frac{M}{ml} = \alpha$ and $J = r^2 M = r^2 \alpha ml$.

Solution. For a cantilever beam, $\lambda_1 = 1.8751$ (see Table 5.3). For a beam with given boundary conditions, the ordinates of eigenfunction X_1 and its derivatives X'_1 for the specified x_1 are taken from Appendix A.1

$$X_1 = 0.4598 \quad \text{and} \quad X'_1 = 2.0452$$

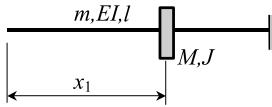

FIGURE 7.27. Design diagram.

Adjustment mass

$$m_1 = m + \frac{1}{l} [X_1^2(\xi)M + X_1'^2(\xi)J] = m + \frac{1}{l} (0.4598^2 \times \alpha ml + 2.0452^2 \times r^2 \alpha ml)$$

$$m_1 = m[1 + \alpha(0.4598^2 + 2.0452^2 \times r^2)]$$

The fundamental frequency of vibration

$$\omega_1 = \frac{1.8751^2}{l^2} \sqrt{\frac{EI}{m[1 + \alpha(0.2114 + 4.1853r^2)]}}$$

The adjustment mass method for multispan beams is presented in Section 9.7.2.

7.7 MODAL SHAPE VIBRATIONS FOR BEAMS WITH CLASSICAL BOUNDARY CONDITIONS

Tables 7.9, 7.10 and 7.11 present the eigenfunctions for beams with different boundary conditions and one lumped mass along the span (Anan'ev, 1946; Gorman, 1975). Notation $\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$, $m = \rho A$, $\xi = \frac{x}{l}$, $\mu = \frac{d}{l}$, $\gamma = \frac{c}{l} = 1 - \mu$.

7.7.1 Clamped beams at the one end, classical boundary condition at the other and with lumped mass along the span (Table 7.9)

Compatibility conditions

1. Compatibility of displacement

$$X_1(\xi)|_{\xi=\mu} = X_1(\xi)|_{\xi=\gamma}$$

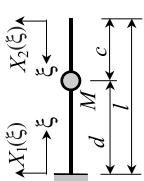

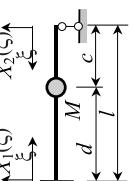

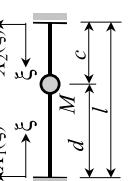

2. Compatibility of slope

$$\left. \frac{dX_1(\xi)}{d\xi} \right|_{\xi=\mu} = - \left. \frac{dX_2(\xi)}{d\xi} \right|_{\xi=\gamma}$$

3. Compatibility of bending moment

$$\left. \frac{d^2X_1(\xi)}{d\xi^2} \right|_{\xi=\mu} = \left. \frac{d^2X_2(\xi)}{d\xi^2} \right|_{\xi=\gamma}$$

TABLE 7.9 One-span uniform beams with one lumped mass a long the span; Mode shape of vibration

Beam type	Modal shapes $X(\xi)$	Matrix D
	$X_1(\xi) = A_1(\sin \lambda \xi - \sinh \lambda \xi) + B_1(\cos \lambda \xi - \cosh \lambda \xi)$ $X_2(\xi) = A_2(\sin \lambda \xi + \sinh \lambda \xi) + B_2(\cos \lambda \xi + \cosh \lambda \xi)$	$A_1 = 1; [B_1 \quad A_2 \quad B_2] = D^{-1} \begin{bmatrix} \sinh \lambda \mu - \sin \lambda \mu \\ \cosh \lambda \mu - \cos \lambda \mu \\ -\sin \lambda \mu - \sinh \lambda \mu \end{bmatrix}$
	$X_1(\xi) = A_1(\sin \lambda \xi - \sinh \lambda \xi) + B_1(\cos \lambda \xi - \cosh \lambda \xi)$ $X_2(\xi) = A_2 \sin \lambda \xi + B_2 \sinh \lambda \xi$	$A_1 = 1; [B_1 \quad A_2 \quad B_2] = D^{-1} \begin{bmatrix} \sinh \lambda \mu - \sin \lambda \mu \\ \cosh \lambda \mu - \cos \lambda \mu \\ \sin \lambda \mu + \sinh \lambda \mu \end{bmatrix}$
	$X_1(\xi) = A_1(\sin \lambda \xi - \sinh \lambda \xi) + B_1(\cos \lambda \xi - \cosh \lambda \xi)$ $X_2(\xi) = A_2(\sin \lambda \xi - \sinh \lambda \xi) + B_2(\cos \lambda \xi - \cosh \lambda \xi)$	$A_1 = 1; [B_1 \quad A_2 \quad B_2] = D^{-1} \begin{bmatrix} \cosh \lambda \mu - \cos \lambda \mu \\ \sinh \lambda \mu - \sin \lambda \mu \\ -\cos \lambda \mu - \cosh \lambda \mu \end{bmatrix}$

4. Compatibility of shear forces (dynamic equilibrium between motion of the lumped mass and adjacent shear forces)

$$\frac{d^3 X_1(\xi)}{d\xi^3} \Big|_{\xi=\mu} + \frac{d^3 X_2(\xi)}{d\xi^3} \Big|_{\xi=\gamma} = -\lambda^4 \frac{M}{ml} X_1(\mu)$$

Frequency equation. The expressions for mode shape vibration and compatibility conditions lead to the four linear homogeneous algebraic equations with respect to coefficients A_1, A_2, B_1 and B_2 . A non-trivial solution exists if the determinant of the coefficients of the matrix of the constants appearing in the four equations is equal to zero.

7.7.2 Pinned beams at the one end, classical boundary condition at the other and with lumped mass along the span (Table 7.10)

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}, \quad m = \rho A, \quad \xi = \frac{x}{l}, \quad \mu = \frac{d}{l}, \quad \gamma = \frac{c}{l} = 1 - \mu$$

Compatibility conditions

1. Compatibility of displacements

$$X_1(\xi)|_{\xi=\mu} = X_1(\xi)|_{\xi=\gamma}$$

2. Compatibility of slopes

$$\frac{dX_1(\xi)}{d\xi} \Big|_{\xi=\mu} = -\frac{dX_2(\xi)}{d\xi} \Big|_{\xi=\gamma}$$

3. Compatibility of bending moments

$$\frac{d^2 X_1(\xi)}{d\xi^2} \Big|_{\xi=\mu} = \frac{d^2 X_2(\xi)}{d\xi^2} \Big|_{\xi=\gamma}$$

4. Compatibility of shear forces (dynamic equilibrium of moving lumped mass)

$$\frac{d^3 X_1(\xi)}{d\xi^3} \Big|_{\xi=\mu} + \frac{d^3 X_2(\xi)}{d\xi^3} \Big|_{\xi=\gamma} = -\lambda^4 \frac{M}{ml} X_1(\mu)$$

7.7.3 Beams with overhang and with lumped mass along the span (Table 7.11)

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}, \quad m = \rho A, \quad \xi = \frac{x}{l}, \quad \mu = \frac{d}{l}, \quad \gamma = \frac{c}{l} = 1 - \mu$$

TABLE 7.10. One-span uniform beams with one lumped mass along the span: Mode shapes of vibration

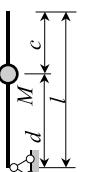

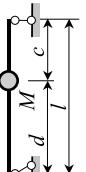

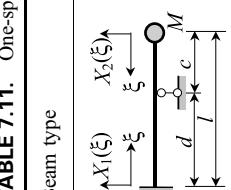

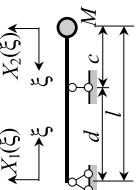

Beam type	Modal shapes $X(\xi)$	Matrix D
	$X_1(\xi) = A_1 \sin \lambda \xi + B_1 \sinh \lambda \xi$ $X_2(\xi) = A_2 (\sin \lambda \xi + \sinh \lambda \xi) + B_2 (\cos \lambda \xi + \cosh \lambda \xi)$ $A_1 = 1; \quad [B_1 \quad A_2 \quad B_2] = D^{-1} \begin{bmatrix} -\sin \lambda \mu \\ -\cos \lambda \mu \\ \sin \lambda \mu \end{bmatrix}$	$\begin{bmatrix} \sinh \lambda \mu & -\sin \lambda \gamma - \sinh \lambda \gamma & -\cos \lambda \gamma - \cosh \lambda \gamma \\ \cosh \lambda \mu & \cos \lambda \gamma + \cosh \lambda \gamma & \sinh \lambda \gamma - \sin \lambda \gamma \\ \sinh \lambda \mu & \sin \lambda \gamma - \sinh \lambda \gamma & \cos \lambda \gamma - \cosh \lambda \gamma \end{bmatrix}$
	$X_1(\xi) = A_1 \sin \lambda \xi + B_1 \sinh \lambda \xi$ $X_2(\xi) = A_2 \sin \lambda \xi + B_2 \sinh \lambda \xi$ $A_1 = 1; \quad [B_1 \quad A_2 \quad B_2] = D^{-1} \begin{bmatrix} -\sin \lambda \mu \\ -\cos \lambda \mu \\ \sin \lambda \mu \end{bmatrix}$	$\begin{bmatrix} \sinh \lambda \mu & -\sin \lambda \gamma - \sinh \lambda \gamma & -\sinh \lambda \gamma \\ \cosh \lambda \mu & \cos \lambda \gamma & \cosh \lambda \gamma \\ \sinh \lambda \mu & \sin \lambda \gamma & -\sinh \lambda \gamma \end{bmatrix}$

TABLE 7.11. One-span uniform beam with one lumped mass at the end of overhang: Mode shapes of vibration

Beam type	Modal shapes $X(\xi)$	Parameters
	$X_1(\xi) = (\sin \lambda\xi - \sinh \lambda\xi + \delta(\cos \lambda\xi - \cosh \lambda\xi))$ $X_2(\xi) = \gamma_1[\sin \lambda\xi + \theta(\cos \lambda\xi + \cosh \lambda\xi) + \alpha(\sinh \lambda\xi + \phi \cos \lambda\xi + \phi \cosh \lambda\xi)]$ $\gamma_1 = \frac{\cosh \lambda\mu - \cos \lambda\mu + \delta(\sin \lambda\mu + \sinh \lambda\mu)}{\cos \lambda\gamma + \theta(\sinh \lambda\gamma - \sin \lambda\gamma) + \alpha(\cosh \lambda\gamma + \phi \sinh \lambda\gamma - \phi \sin \lambda\gamma)}$	$\delta = \frac{\sinh \lambda\mu - \sin \lambda\mu}{\cos \lambda\mu - \cosh \lambda\mu} \quad \alpha = \frac{\eta + 2\theta\lambda}{\eta - 2\phi\lambda}$ $\theta = -\frac{\cos \lambda\gamma + \cosh \lambda\gamma}{\sin \lambda\gamma + \sinh \lambda\gamma}$ $\phi = -\frac{\cos \lambda\gamma + \cosh \lambda\gamma}{\sinh \lambda\gamma + \sin \lambda\gamma}$
	$X_1(\xi) = \sin \lambda\xi - \frac{\sin \lambda\mu}{\sinh \lambda\mu} \sinh \lambda\xi$ $X_2(\xi) = \gamma_1[\sin \lambda\xi + \theta(\cos \lambda\xi + \cosh \lambda\xi) + \alpha(\sinh \lambda\xi + \phi \cos \lambda\xi + \phi \cosh \lambda\xi)]$ $\gamma_1 = \frac{\sin \lambda\mu - \cosh \lambda\mu}{\cosh \lambda\mu - \sinh \lambda\mu - \cos \lambda\mu} \quad \theta = -\frac{\sin \lambda\gamma + \cosh \lambda\gamma}{\cos \lambda\gamma + \sinh \lambda\gamma}$	$\alpha = \frac{\eta + 2\theta\lambda}{\eta - 2\phi\lambda}$ $\phi = -\frac{\sinh \lambda\gamma + \sin \lambda\gamma}{\cos \lambda\gamma + \cosh \lambda\gamma}$

7.8 BEAMS WITH CLASSIC BOUNDARY CONDITIONS AT ONE END AND A TRANSLATIONAL SPRING SUPPORT AND LUMPED MASS AT THE OTHER

A beam with pinned or clamped boundary conditions at the left-hand end and non-classical boundary condition at the right-hand end is shown in Fig. 7.29.

The natural frequency of vibration is

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}, \quad m = \rho A$$

Frequency parameters λ are roots of a frequency equation. The exact solutions of the eigenvalue and eigenfunction problem (frequency equation and mode shape of vibration) for beams with classic boundary conditions at the left-hand end and a lumped mass with elastic support at the right-hand end are presented in Table 7.12 (Anan'ev, 1946; Gorman, 1975). Dimensionless parameters are

$$\eta = \frac{ml}{M} \quad M^* = \eta^{-1} \quad k^* = \frac{k l^3}{EI} \quad \alpha = \frac{\eta}{k^*} \quad \omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$$

Numerical results. Eigenvalues λ as a function of mass ratio and stiffness ratio for the fundamental mode of vibration are shown in Fig. 7.30 (left end is pinned) and Fig. 7.31 (left end is clamped) (Anan'ev, 1946).

Example. Beam clamped at the one end with a translational spring support and lumped mass at other end. Calculate the mass parameter η which leads to the frequency parameter $\lambda = 1.2$ if the relative stiffness $k^* = \frac{k l^3}{EI} = 10$.

Solution. Hohenemser–Prager functions at $\lambda = 1.2$ are $E(1.2) = 1.65611$, and $B(1.2) = 1.14064$.

The algebraic equation with respect to parameter α is

$$10^2 + 10 \times \frac{1.2^3 \times 1.65611}{1.14064} - \frac{1.2^4}{\alpha} = 0$$

and the root of the frequency equation is $\alpha = 0.01657699$.

The mass parameter is $\eta = \alpha k^* = 0.1657699$ and the relative mass is

$$\frac{M}{ml} = \frac{1}{\alpha k^*} = 6.0324$$

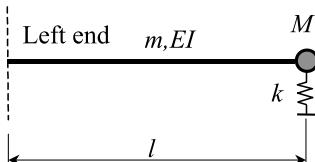

FIGURE 7.29. Design diagram of a beam; the left-hand end of the beam is pinned, or clamped.

TABLE 7.12. Frequency equation and mode shape of vibration for beams with classical boundary conditions at the left-hand end and with a translational spring support and lumped mass at the other end

Left end	Frequency equation (two forms)	Mode shape $X(\xi)$, $0 \leq \xi \leq 1$
Pinned	$(k^*)^2 + k^* \frac{\lambda^3 (\cos \lambda \sinh \lambda - \sin \lambda \cosh \lambda)}{2 \sin \lambda \sinh \lambda} - \frac{\lambda^4}{\alpha} = 0$ $(k^*)^2 - k^* \frac{\lambda^3 B(\lambda)}{S_1(\lambda)} - \frac{\lambda^4}{\alpha} = 0$	$\sin \lambda \xi + \gamma \sinh \lambda \xi$ $\gamma = \frac{\sin \lambda}{\sinh \lambda}$
Clamped	$(k^*)^2 + k^* \frac{\lambda^3 (1 + \cos \lambda \cosh \lambda)}{\sin \lambda \cosh \lambda - \sinh \lambda \cos \lambda} - \frac{\lambda^4}{\alpha} = 0$ $(k^*)^2 + k^* \frac{\lambda^3 E(\lambda)}{B(\lambda)} - \frac{\lambda^4}{\alpha} = 0$	$\sin \lambda \xi - \sinh \lambda \xi + \gamma (\cos \lambda \xi - \cosh \lambda \xi)$ $\gamma = - \frac{\sin \lambda + \sinh \lambda}{\cos \lambda + \cosh \lambda}$

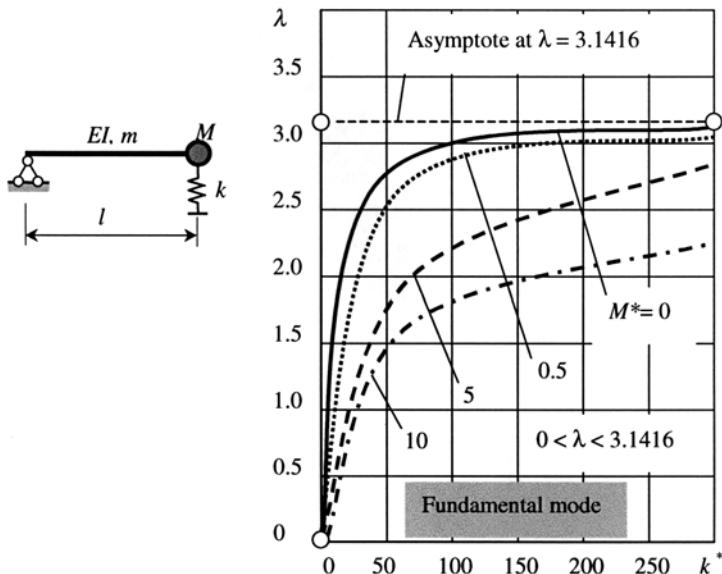

FIGURE 7.30. Fundamental mode of vibration. Parameter λ as a function of mass ratio $M^* = M/ml$ and stiffness ratio $k^* = kl^3/EI$.

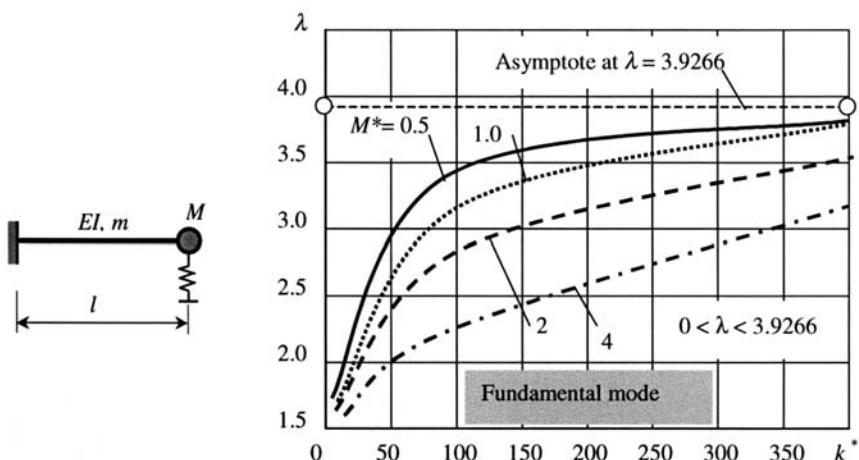

FIGURE 7.31. Fundamental mode of vibration. Parameter λ as a function of mass ratio $M^* = M/ml$ and stiffness ratio $k^* = kl^3/EI$.

Example. Consider a beam pinned at one end with a translational spring support and lumped mass at other end.

Derive the expression for stiffness parameter k^* that leads to the frequency parameter λ if the relative mass $M^* = \frac{M}{m}$.

Solution. The frequency equation leads to the following expression for the stiffness parameter

$$k^* = \lambda^4 M^* + \lambda^3 \frac{\sin \lambda \cosh \lambda - \cos \lambda \sinh \lambda}{2 \sin \lambda \sinh \lambda}$$

7.9 BEAMS WITH ROTATIONAL MASS

7.9.1 Beams with rotational mass at the pinned end and classical boundary condition at the other

The beam with classical boundary conditions at the left-hand end and a rotational mass (J_0 is the rotational moment of inertia of the mass) at the right-hand end is shown in Fig. 7.32.

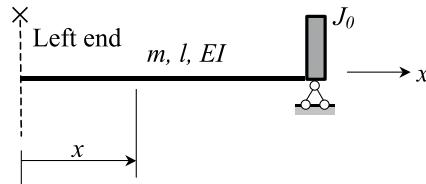

FIGURE 7.32. Design diagram of the beam and notation; the left-hand end of the beam is free, or pinned, or clamped.

7.9.2 Frequency equation and mode shape of vibration for beams with different boundary conditions (left-hand end) with a point rotational mass of the pinned right-hand end

The natural frequency of vibration is

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}, \quad m = \rho A l$$

Frequency parameters λ are the roots of a frequency equation. The exact solution of the eigenvalue and eigenfunction problem (frequency equation and mode shape of vibration) for beams with classical and non-classical boundary conditions at the left-hand end and a rotational mass at one end are presented in Tables 7.13–7.15 (Anan'ev, 1946; Gorman, 1975).

Dimensionless parameters are

$$\xi = \frac{x}{l}, \quad J^* = \frac{\rho A l^3}{J_0}$$

TABLE 7.13. One-span uniform beams with rotational mass at the pinned end: Frequency equation and mode shape of vibration.

Left end	Frequency equation	Mode shape $X(\xi)$	Parameter γ
Free	$J^* = \lambda^3 \frac{1 + \cos \lambda \cosh \lambda}{\sinh \lambda \cos \lambda - \sin \lambda \cosh \lambda}$	$\sin \lambda \xi + \sinh \lambda \xi + \gamma(\cos \lambda \xi + \cosh \lambda \xi)$	$-\frac{\sin \lambda + \sinh \lambda}{\cos \lambda + \cosh \lambda}$
Pinned	$J^* = \lambda^3 \frac{\sin \lambda \cosh \lambda - \cos \lambda \sinh \lambda}{2 \sin \lambda \sinh \lambda}$	$\sin \lambda \xi + \gamma \sinh \lambda \xi$	$-\frac{\sin \lambda}{\sinh \lambda}$
Clamped	$J^* = \lambda^3 \frac{1 - \cos \lambda \cosh \lambda}{\sin \lambda \cosh \lambda - \sinh \lambda \cos \lambda}$	$\sin \lambda \xi - \sinh \lambda \xi + \gamma(\cos \lambda \xi - \cosh \lambda \xi)$	$\frac{\sinh \lambda - \sin \lambda}{\cos \lambda - \cosh \lambda}$

Example. Find the fundamental frequency of vibration and mode shape vibration for a clamped-pinned beam with a rotational mass at the pinned end. Assume the parameter

$$J^* = \frac{\rho A l^3}{J_0} = 34.767.$$

Solution. The minimal root of equation

$$J^* = \lambda^3 \frac{1 - \cos \lambda \cosh \lambda}{\sin \lambda \cosh \lambda - \sinh \lambda \cos \lambda}$$

is $\lambda = 1.48$.

The fundamental frequency of vibration is

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}} = \frac{1.48^2}{l^2} \sqrt{\frac{EI}{m}}, \quad m = \rho A$$

Parameter λ according to Table 7.13 is calculated by

$$\gamma(1.48) = \frac{\sinh \lambda - \sin \lambda}{\cos \lambda - \cosh \lambda} = -0.48962$$

Mode shape

$$X(\xi) = \sin 1.48\xi - \sinh 1.48\xi - 0.48962(\cos 1.48\xi - \cosh 1.48\xi), \quad \xi = x/l$$

Frequency equation for special cases (Table 5.3)

1. $J_0 = 0$

$$\text{Free-pinned beam} \quad \sinh \lambda \cos \lambda - \sin \lambda \cosh \lambda = 0$$

$$\text{Pinned-pinned beam} \quad \sin \lambda = 0$$

$$\text{Clamped-pinned beam} \quad \sin \lambda \cosh \lambda - \sinh \lambda \cos \lambda = 0$$

2. $J_0 = \infty$ In this case, the pinned support at the right-hand end converts to a clamped support

$$\text{Free-pinned beam} \rightarrow \text{Free-clamped beam:} \quad 1 + \cos \lambda \cosh \lambda = 0$$

$$\text{Pinned-pinned beam} \rightarrow \text{Pinned-clamped beam:} \quad \tan \lambda - \tanh \lambda = 0$$

$$\text{Clamped-pinned beam} \rightarrow \text{Clamped-clamped beam:} \quad 1 - \cos \lambda \cosh \lambda = 0$$

7.9.3 Beams with rotational mass at the pinned end and a non-classical boundary condition at the other

Design diagrams and corresponding frequency equations and eigenfunctions are presented in Table 7.14 (Anan'ev, 1946; Gorman, 1975). Dimensionless parameters are

$$J^* = \frac{ml^3}{J}, k_{\text{tr}}^* = \frac{k_{\text{tr}}l^3}{EI}, k_{\text{rot}}^* = \frac{k_{\text{rot}}l}{EI}, \xi = \frac{x}{l}.$$

TABLE 7.14. One-span uniform beams with rotational masses at the pinned ends: Frequency equation and mode shape of vibration

	$(k_{\text{rot}}^*)^2 + k_{\text{rot}}^* \frac{\lambda(\sin \lambda \cosh \lambda - \cos \lambda \sinh \lambda)}{1 - \cos \lambda \cosh \lambda} - \frac{\lambda^4}{\alpha} = 0$ $X(\xi) = \sin \lambda \xi - \frac{\sin \lambda}{\sinh \lambda} \sinh \lambda \xi + \gamma (\cos \lambda \xi - \cosh \lambda \xi + \gamma_2 \sinh \lambda \xi)$	$\gamma = \frac{\sin \lambda \sinh \lambda - \sin \lambda \cosh \lambda}{\cos \lambda \sinh \lambda + \cos \lambda \cosh \lambda + \sinh^2 \lambda - \cosh^2 \lambda}$ $\gamma_2 = \frac{\cosh \lambda - \cos \lambda}{\sinh \lambda}$

7.9.4 Beams with a pinned rotational mass and torsional spring at the left-hand end and classical boundary conditions at the right-hand end

Design diagrams and corresponding frequency equations and the expressions for eigenfunctions are presented in Table 7.15 (Anan'ev, 1946; Gorman, 1975). Dimensionless parameters are

$$J^* = \frac{ml^3}{J}, k_{\text{rot}}^* = \frac{k_{\text{rot}}l}{EI}, \alpha = \frac{J^*}{k_{\text{rot}}^*}, \gamma_1 = \frac{2\lambda}{k_{\text{rot}}^* - \frac{\lambda^4}{J^*}}$$

7.10 BEAMS WITH ROTATIONAL AND LUMPED MASSES

Design diagrams and the exact solution of the eigenvalue and eigenfunction problem are presented in Tables 7.13–7.16 (Anan'ev, 1946; Gorman, 1975). The natural frequency of vibration is $\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$, $m = \rho A$. Dimensionless parameters are $J^* = \frac{ml^3}{J}$, $\eta_i = \frac{ml}{M_i}$, where J is the rotational moment of inertia of mass; M is a lumped mass. Frequency parameters λ are roots of a frequency equation.

Example. Consider a design beam with two lumped masses at the free ends (Table 7.16). Find the ratio $\alpha = \eta_2/\eta_1 = M_1/M_2$ for $\eta_2 = ml/M_2 = 10$ which leads to $\lambda = 4$.

Solution. The frequency equation from Table 7.16, case 1, may be rewritten by using Hohenemser–Prager functions in the form

$$\frac{M_1}{M_2} + \frac{n_2 \lambda B(\lambda) - D(\lambda)}{n_2^2 \lambda^2 S_1(\lambda) + n_2 \lambda B(\lambda)} = 0, \quad n_2 = \frac{1}{\eta_2} = 0.1$$

$$\frac{M_1}{M_2} + \frac{0.1 \times 4.0 \times (-2.82906) - (-18.84985)}{0.1^2 \times 4^2 \times (-41.30615) + 0.1 \times 4.0 \times (-2.82906)} = 0$$

This equation leads to the following parameter

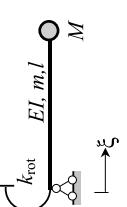

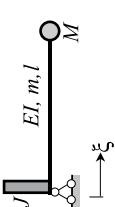

$$\alpha = \eta_2/\eta_1 = M_1/M_2 = 2.28899$$

Numerical results for a beam having two lumped masses at the free ends with different mass parameters $\alpha = M_1/M_2$ and $n_2 = M_2/ml$ are presented in Fig. 7.33.

7.11 BEAMS WITH ATTACHED BODY OF A FINITE LENGTH

This section is devoted to the vibration of a clamped–free beam with a body at the free end. The length of the body is taken into account. The motion of a structure may be restricted by torsional or translational elastic spring supports, which are attached at the free end.

TABLE 7.16. One-span uniform beams with lumped and rotational masses: Frequency equation and mode shape of vibration

Beam type	Frequency equation and mode shape $X(\xi)$	Parameters
	$(\eta_1)^2 + \eta_1 \frac{\lambda(1+\alpha)(\sin \lambda \cosh \lambda - \cos \lambda \sinh \lambda)}{\alpha(1-\cos \lambda \cosh \lambda)} + \frac{2\lambda^2 \sin \lambda \sinh \lambda}{\alpha(1-\cos \lambda \cosh \lambda)} = 0$ $\gamma = \frac{\sin \lambda - \sinh \lambda}{\cosh \lambda - \cos \lambda + 2 \frac{\lambda}{\eta_1} \sinh \lambda}$	
	$X(\xi) = \sin \lambda \xi + \sinh \lambda \xi + \gamma \left(\cos \lambda \xi + \cosh \lambda \xi + 2 \frac{\lambda}{\eta_1} \sinh \lambda \xi \right)$ $\alpha = \frac{\eta_2}{\eta_1}$	
	$(k_{\text{rot}}^*)^2 + k_{\text{rot}}^* \frac{\lambda(1+\alpha)(\cos \lambda \sinh \lambda - \sin \lambda \cosh \lambda)}{\alpha(1+\cos \lambda \cosh \lambda)} - \frac{2\lambda^2 \sin \lambda \sinh \lambda}{\alpha(1+\cos \lambda \cosh \lambda)} = 0$ $\gamma = \frac{-(\sin \lambda + \sinh \lambda)}{\cos \lambda + \cosh \lambda + 2 \frac{\lambda}{k_{\text{rot}}^*} \sinh \lambda}$	
	$X(\xi) = \sin \lambda \xi - \sinh \lambda \xi + \gamma \left(\cos \lambda \xi - \cosh \lambda \xi - 2 \frac{\lambda}{k_{\text{rot}}^*} \sinh \lambda \xi \right)$ $\alpha = \frac{\eta}{k_{\text{rot}}^*}$	
	$\eta^2 + \eta \frac{1 + \cos \lambda \cosh \lambda + 2 \frac{\alpha}{\lambda^2} \sin \lambda \sinh \lambda}{\frac{\alpha}{\lambda^3} (\cosh \lambda \sin \lambda - \sinh \lambda \cos \lambda)} - \frac{\lambda^4}{\alpha} = 0$ $\gamma = \frac{\sinh \lambda + \sin \lambda}{2 \frac{J^*}{\lambda^3} \sinh \lambda - (\cos \lambda + \cosh \lambda)}$	
	$X(\xi) = \sin \lambda \xi - \sinh \lambda \xi + \gamma \left(\cos \lambda \xi - \cosh \lambda \xi + \frac{2J^*}{\lambda^3} \sinh \lambda \xi \right)$ $\alpha = \frac{J^*}{\eta}$	

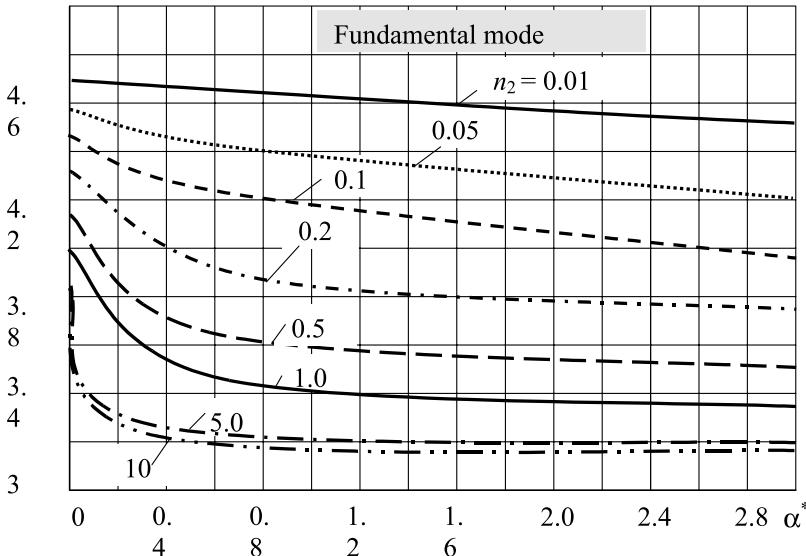

FIGURE 7.33. Free-free beam with two different tip masses. Fundamental mode vibration. Parameter λ as a function of mass ratios α^* and n_2 .

The natural frequencies of vibration are $\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$, $m = \rho A$. Frequency parameters λ are the roots of a frequency equation. (Table 7.16, case 1).

7.11.1 Beam with a heavy tip body

A cantilever beam with a body attached at the free end is presented in Fig. 7.34.

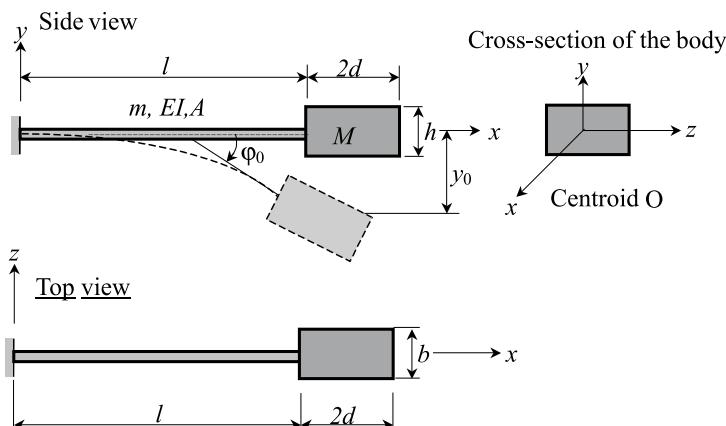

FIGURE 7.34. Design diagram.

The parameters of a body are:

$2d, b, h$ = length, width, and height

J = moment of the rotary inertia of the body with respect to the z -axis passing through the centroid

ρ_z = radius gyration of the body, $\rho_z^2 = J/M$

M = mass of the body

Displacements of a body at $x = l$

$$\phi_0 = \frac{\partial y}{\partial x} \Big|_{x=l} \quad y_0 = y(l, t) + d \frac{\partial y}{\partial x} \Big|_{x=1} \quad (7.23)$$

Differential equation of motion for mass M

$$M \frac{\partial^2 y_0}{\partial t^2} = -Q(l, t), \quad M \rho_z^2 \frac{\partial^2 \phi_0}{\partial t^2} = Qd - EI \frac{\partial^2 y}{\partial x^2} \Big|_{x=l} \quad Q(l, t) = -EI \frac{\partial^3 y}{\partial x^3} \Big|_{x=1} \quad (7.24)$$

Boundary conditions at $x = l$

$$\begin{aligned} -EI \frac{\partial^3 y}{\partial x^3} + M \frac{\partial^2 y}{\partial t^2} + Md \frac{\partial^3 y}{\partial t^2 \partial x} &= 0 \\ EI d \frac{\partial^3 y}{\partial x^3} + EI \frac{\partial^2 y}{\partial x^2} + M \rho_z^2 \frac{\partial^3 y}{\partial t^2 \partial x} &= 0 \end{aligned} \quad (7.25)$$

The normal function is

$$X(x) = CU(x) + DV(x)$$

where $U(x)$ and $V(x)$ are Krylov–Duncan functions.

The frequency equation may be presented as follows (Filippov, 1970)

$$\begin{aligned} \frac{1}{\alpha} (1 + \cosh \lambda \cos \lambda) - \lambda (\sin \lambda \cosh \lambda - \cos \lambda \sinh \lambda) - 2\epsilon \lambda^2 \sin \lambda \sinh \lambda \\ - (\delta + \epsilon^2) (\sin \lambda \cosh \lambda + \cos \lambda \sinh \lambda) \lambda^3 + \alpha \delta \lambda^4 (1 - \cos \lambda \cosh \lambda) = 0 \end{aligned} \quad (7.26)$$

where the dimensionless parameters are

$$\alpha = \frac{M}{\rho A l}; \quad \delta = \frac{\rho_z^2}{l^2}; \quad \epsilon = \frac{d}{l}$$

Special cases

1. A cantilever beam with a lumped mass at the free end ($\epsilon = 0, \delta = 0$)

$$\frac{1}{\alpha} (1 + \cosh \lambda \cos \lambda) - \lambda (\sin \lambda \cosh \lambda - \cos \lambda \sinh \lambda) = 0 \quad (\text{see Table 7.6})$$

2. A clamped–free beam ($\alpha = 0$)

$$1 + \cosh \lambda \cos \lambda = 0 \quad (\text{see Table 5.3})$$

7.11.2 Beam with a heavy tip body and rotational spring at the free end

A cantilever beam with an attached body and elastic rotational spring support at the free end is presented in Fig. 7.35. The parameters of a body are described in Section 7.11.1.

Boundary conditions

$$\begin{aligned} \text{at } x = 0: \quad & y(0) = 0, \quad \frac{\partial y}{\partial x} = 0 \\ \text{at } x = l: \quad & -EI \frac{\partial^2 y}{\partial x^2} = (J + Md^2) \frac{\partial^3 y}{\partial x \partial t^2} + M \frac{d \partial^2 y}{\partial t^2} + K_{\text{rot}} \frac{\partial y}{\partial x}, \\ & EI \frac{\partial^3 y}{\partial x^3} = M \frac{\partial^2 y}{\partial t^2} + Md \frac{\partial^3 y}{\partial x \partial t^2} \end{aligned} \quad (7.27)$$

The frequency equation may be presented as follows (Maurizi *et al.*, 1990)

$$\begin{aligned} (J^* M^* \lambda^4 - K_{\text{rot}}^* M^*) (1 - \cosh \lambda \cos \lambda) - \left\{ (J^* + M^* d^{*2}) \lambda^3 \right. \\ \left. - \frac{K_{\text{rot}}^*}{\lambda} \right\} (\sin \lambda \cosh \lambda + \cos \lambda \sinh \lambda) - 2\lambda^2 M^* d^* \sin \lambda \sinh \lambda \\ + M^* \lambda (\sinh \lambda \cos \lambda - \sin \lambda \cosh \lambda) + (1 + \cos \lambda \cosh \lambda) = 0 \end{aligned} \quad (7.28)$$

where the dimensionless parameters are

$$d^* = \frac{d}{l}, \quad J^* = \frac{J}{M_{\text{beam}} l^2}, \quad M^* = \frac{M}{M_{\text{beam}}}, \quad K_{\text{rot}}^* = \frac{K_{\text{rot}} l}{EI}$$

Frequency equations for special cases

1. Cantilever beam ($M = 0, J = 0, d = 0, K_{\text{rot}} = 0$) (see Table 5.3)

$$\boxed{-} \quad 1 + \cos \lambda \cosh \lambda = 0$$

2. Cantilever beam with lumped mass at the end ($J = 0, d = 0, K_{\text{rot}} = 0$) (see Table 7.6)

$$\boxed{- \bullet} \quad M^* \lambda (\sinh \lambda \cos \lambda - \sin \lambda \cosh \lambda) + (1 + \cos \lambda \cosh \lambda) = 0$$

3. Cantilever beam with torsional spring at the free end ($J = 0, d = 0, M = 0$) (see Tables 6.9 and 6.12)

$$\boxed{-} \quad -\frac{K_{\text{rot}}^*}{\lambda} (\sin \lambda \cosh \lambda + \cos \lambda \sinh \lambda) + (1 + \cos \lambda \cosh \lambda) = 0$$

4. Clamped-clamped beam ($J = 0, d = 0, K_{\text{rot}} \rightarrow \infty$) (see Table 5.3)

$$\boxed{- \parallel} \quad 1 - \cosh \lambda \cos \lambda = 0$$

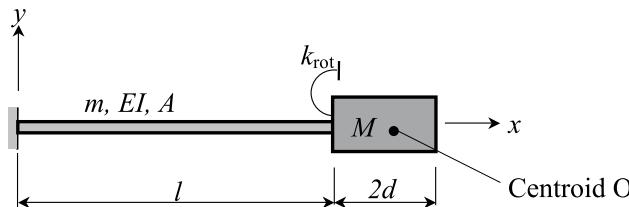

FIGURE 7.35. Design diagram.

7.11.3 Beam with a body and translational spring at the free end

A cantilever beam with an attached body and elastic translational spring support at the free end is presented in Fig. 7.36. The parameters of the body are described in Section 7.11.1.

Boundary conditions

$$\begin{aligned} \text{at } x = 0: \quad & y(0) = 0, \quad \frac{\partial y}{\partial x} = 0 \\ \text{at } x = l: \quad & -EI \frac{\partial^2 y}{\partial x^2} = (J + Md^2) \frac{\partial^3 y}{\partial x \partial t^2} + Md \frac{\partial^2 y}{\partial t^2}, \\ & EI \frac{\partial^3 y}{\partial x^3} = M \frac{\partial^2 y}{\partial t^2} + Md \frac{\partial^3 y}{\partial x \partial t^2} + K_{tr}y \end{aligned} \quad (7.29)$$

The frequency equation may be presented as follows (Maurizi *et al.*, 1990):

$$\begin{aligned} & [J^*M^*\lambda^4 - (J^* + M^*d^{*2})K_{tr}](1 - \cosh \lambda \cos \lambda) \\ & - (J^* + M^*d^{*2})\lambda^3(\sin \lambda \cosh \lambda + \cos \lambda \sinh \lambda) - 2\lambda^2 M^*d^* \sin \lambda \sinh \lambda \\ & + \left(M^*\lambda - \frac{K_{tr}^*}{\lambda^3} \right)(\sinh \lambda \cos \lambda - \sin \lambda \cosh \lambda) + (1 + \cos \lambda \cosh \lambda) = 0 \end{aligned} \quad (7.30)$$

where the dimensionless parameters are

$$d^* = \frac{d}{l}, \quad J^* = \frac{J}{M_{beam}l^2}, \quad M^* = \frac{M}{M_{beam}}, \quad K_{tr}^* = \frac{K_{tr}l^3}{EI}$$

Special cases

1. Cantilever beam ($M = 0, J = 0, d = 0, K_{tr} = 0$) (see Table 5.3).
2. Cantilever beam with lumped mass at the free end ($J = 0, d = 0, K_{tr} = 0$) (see Table 7.6).
3. Cantilever beam with spring at the end ($J = 0, d = 0, M = 0$) (see Table 6.6; Section 6.2.3).

$$-\frac{K_{tr}^*}{\lambda^3}(\sinh \lambda \cos \lambda - \cosh \lambda \sin \lambda) + (1 + \cos \lambda \cosh \lambda) = 0$$

4. Clamped-pinned beam ($J = 0, d = 0, K_{tr} \rightarrow \infty$) (see Table 5.3).

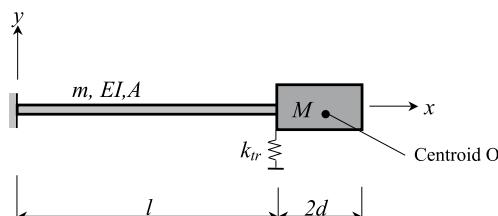

FIGURE 7.36. Design diagram.

7.12 PINNED-ELASTIC SUPPORT BEAM WITH OVERHANG AND LUMPED MASSES

Figure 7.37 presents a beam with uniformly distributed load and lumped masses that are attached at x_1 , $x_2 = l_1$ and $x_3 = l$. The beam is pinned at $x = 0$ and elastic supported at $x = l_1 < l$.

The natural frequency of vibration is defined as

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m(1+e)}}$$

The frequency parameters λ are roots of a frequency equation; this equation may be presented as follows (Filippov, 1970)

$$\gamma_1 \delta_2 - \gamma_2 \delta_1 = 0 \quad (7.31)$$

$$\begin{aligned}\gamma_1 &= \sinh \lambda + \frac{\alpha_1}{2} \lambda (\sinh \lambda \eta_1 + \sin \lambda \eta_1) \sinh \lambda \xi_1 - \frac{1}{2} \left(\frac{R}{\lambda^3} - \alpha_2 \lambda \right) (\sinh \lambda \eta_2 + \sin \lambda \eta_2) X_1(\xi_2) \\ \delta_1 &= -\sin \lambda + \frac{\alpha_1}{2} \lambda (\sinh \lambda \eta_1 + \sin \lambda \eta_1) \sin \lambda \xi_1 - \frac{1}{2} \left(\frac{R}{\lambda^3} - \alpha_2 \lambda \right) (\sinh \lambda \eta_2 + \sin \lambda \eta_2) X_2(\xi_2) \\ \gamma_2 &= \cosh \lambda + \frac{\alpha_1}{2} \lambda (\cosh \lambda \eta_1 + \cos \lambda \eta_1) \sinh \lambda \xi_1 \\ &\quad - \frac{1}{2} \left(\frac{R}{\lambda^3} - \alpha_2 \lambda \right) (\cosh \lambda \eta_2 + \cos \lambda \eta_2) X_1(\xi_2) \\ &\quad + \lambda \alpha_3 \left[\sinh \lambda + \frac{\alpha_1}{2} \lambda (\sinh \lambda \eta_1 - \sin \lambda \eta_1) \sinh \lambda \xi_1 \right. \\ &\quad \left. - \frac{1}{2} \left(\frac{R}{\lambda^3} - \alpha_2 \lambda \right) (\sinh \lambda \eta_2 - \sin \lambda \eta_2) \right] X_1(\xi_2) \\ \delta_2 &= -\cos \lambda + \frac{\alpha_1}{2} \lambda (\cosh \lambda \eta_1 + \cos \lambda \eta_1) \sin \lambda \xi_1 \\ &\quad - \frac{1}{2} \left(\frac{R}{\lambda^3} - \alpha_2 \lambda \right) (\cosh \lambda \eta_2 + \cos \lambda \eta_2) X_2(\xi_2) \\ &\quad + \lambda \alpha_3 \left[\sin \lambda + \frac{\alpha_1}{2} \lambda (\sinh \lambda \eta_1 - \sin \lambda \eta_1) \sin \lambda \xi_1 \right. \\ &\quad \left. - \frac{1}{2} \left(\frac{R}{\lambda^3} - \alpha_2 \lambda \right) (\sinh \lambda \eta_2 - \sin \lambda \eta_2) X_2(\xi_2) \right]\end{aligned}$$

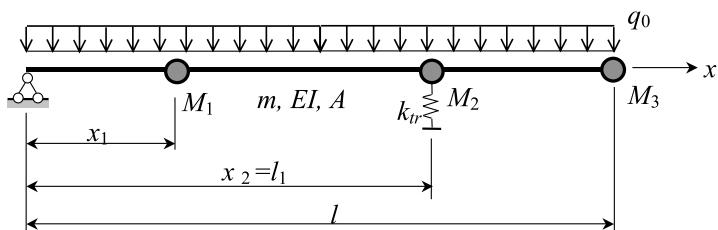

FIGURE 7.37. Design diagram.

where the dimensionless parameters are

$$\begin{aligned}\xi_1 &= \frac{x_1}{l}; \quad \xi_2 = \frac{x_2}{l}; \quad \eta_1 = 1 - \xi_1; \quad \eta_2 = 1 - \xi_2 \\ \alpha_1 &= \frac{M_1}{q}; \quad \alpha_2 = \frac{M_2}{q}; \quad \alpha_3 = \frac{M_3}{q} \\ q &= (1 + e)ml; \quad e = \frac{q_0}{gm}; \quad R = \frac{k_{tr}l^3}{EI}\end{aligned}$$

The mode shapes of vibration are

$$\begin{aligned}X_1(\xi_2) &= \sinh \lambda \xi_2 + \frac{\alpha_1}{2} \lambda [\sinh \lambda (\xi_2 - \xi_1) - \sin \lambda (\xi_2 - \xi_1)] \sinh \lambda \xi_1 \\ X_2(\xi_2) &= \sin \lambda \xi_2 + \frac{\alpha_1}{2} \lambda [\sinh \lambda (\xi_2 - \xi_1) - \sin \lambda (\xi_2 - \xi_1)] \sin \lambda \xi_1\end{aligned}\tag{7.32}$$

Special cases

1. Pinned-free beam ($k_{tr} = 0, M_1 = M_2 = M_3 = 0$) (see Table 5.3).
2. Pinned-free beam with lumped mass at the free end ($k_{tr} = 0, M_1 = M_2 = 0$) (see Table 7.6).
3. Pinned-pinned beam with overhang ($k_{tr} = \infty, M_1 = M_2 = M_3 = 0$) (see Section 5.3).
4. Pinned beam with elasic support $M_1 = M_2 = M_3 = 0$ (see Table 6.6).

BERNOULLI-EULER BEAMS WITH LUMPED AND ROTATIONAL MASSES

CHAPTER 8

BERNOULLI-EULER BEAMS ON ELASTIC LINEAR FOUNDATION

Chapter 8 describes the different mathematical models of an elastic foundation. A mechanical model of the Winkler model is discussed and natural frequencies of vibration of Bernoulli–Euler uniform and stepped one-span beams with different boundary conditions on the elastic foundation are presented.

NOTATION

A	Cross-sectional area of the beam
d	Viscous damping coefficient of foundation
E_0	Elastic constant of the foundation material
E, G	Modulus of elasticity and shear modulus of the beam material
EI	Bending stiffness
G_0	Foundation modulus of rigidity (Pasternak model)
I	Moment of inertia of a cross-sectional area of the beam
k_n	Frequency parameter, $k_n^4 = \frac{m\omega^2 - k_0}{EI}$
k	Shear factor
k_{slope}, D_0	Elastic sloping stiffness of medium
k_{tilt}	Elastic tilting (transverse rotating) stiffness of medium [Nm/m]
k_{tr}, k_0	Elastic transverse translatory stiffness of medium (Winkler foundation modulus)
l	Length of the beam
M	Lumped mass
p	Foundation reaction
t	Time
V_i	Puzyrevsky functions
x	Spatial coordinate
$X(x)$	Mode shape
x, y, z	Cartesian coordinates

$y(x, t)$, w	Lateral displacement of the beam
α	Frequency parameter, $k^4 = -4\alpha^4$
λ	Frequency parameter, $\lambda^2 = k^2 l^2$
θ	Slope
ρ, m	Density of material and mass per unit length of beam, $m = \rho A$
ω	Natural frequency of free transverse vibration

8.1 MODELS OF FOUNDATION

The differential equation of the transverse vibration of a beam on an elastic foundation is

$$EI \frac{\partial^4 y}{\partial x^4} + N \frac{\partial^2 y}{\partial x^2} + \rho A \frac{\partial^2 y}{\partial t^2} + p(y, t) = 0 \quad (8.1)$$

where N is the axial force and $p(y, t)$ is the reaction of the foundation.

The models of the foundation describe the relation between the reaction of the foundation (or pressure) p , the deflection of the beam and the parameters of foundation.

8.8.1 Winkler foundation (Winkler, 1867)

The foundation may be presented as closely spaced independent linear springs. The foundation reaction equals $p = k_0 y$, where y is the vertical deflection of the foundation surface (vertical deflection of the beam, plate), and k_0 is Winkler's foundation modulus. Shear interactions between the foundation spring elements are neglected. This type of foundation is equivalent to a liquid base.

8.1.2 Viscoelastic Winkler foundation

The foundation reaction equals

$$p = k_0 y + d \frac{\partial y}{\partial t} \quad (8.2)$$

where second term takes into account the viscoelastic properties of the Winkler foundation; d is viscous damping coefficient of the foundation.

The governing equation is

$$EI \frac{\partial^4 y}{\partial x^4} + N \frac{\partial^2 y}{\partial x^2} + \rho A \frac{\partial^2 y}{\partial t^2} + k_0 y + d \frac{\partial y}{\partial t} = 0 \quad (8.3)$$

8.1.3 Hetenyi foundation (Hetenyi, 1946)

The relationship between load p and deflection y for the three-dimensional case is

$$p = k_0 y + D_0 \nabla^2 \nabla^2 y \quad (8.4)$$

where the parameter D takes into account the interaction of the spring elements.

8.1.4 Viscoelastic Hetenyi foundation

$$p = k_0 y + d \frac{\partial y}{\partial t} + D_0 \nabla^2 \nabla^2 y \quad (8.5)$$

The governing equation is

$$(EI + D_0) \frac{\partial^4 y}{\partial x^4} + N \frac{\partial^2 y}{\partial x^2} + \rho A \frac{\partial^2 y}{\partial t^2} + k_0 y + d \frac{\partial y}{\partial t} = 0 \quad (8.6)$$

In this model, the overall bending stiffness beam (EI) has been increased by the ‘bending stiffness’ of the foundation (term D_0).

8.1.5 Pasternak foundation (Pasternak, 1954)

The load-deflection relation is

$$p = k_0 y - G_0 \nabla^2 y \quad (8.7)$$

where the second term describes the effect of the shear interactions between the spring elements; G_0 is the shear foundation.

8.1.6 Viscoelastic Pasternak foundation

The load-deflection relation

$$p = k_0 y + d \frac{\partial y}{\partial t} - G_0 \nabla^2 y \quad (8.7a)$$

takes into account the viscoelastic properties of the Pasternak foundation; d is the viscous damping coefficient of the foundation.

The governing equation is

$$EI \frac{\partial^4 y}{\partial x^4} + (N - G_0) \frac{\partial^2 y}{\partial x^2} + \rho A \frac{\partial^2 y}{\partial t^2} + k_0 y + d \frac{\partial y}{\partial t} = 0 \quad (8.8)$$

In this model, the effect of the compressive static load (N) has been reduced by the effective foundation shear (term G_0).

Some fundamental characteristics of the Pasternak foundation mathematical model are discussed by Kerr (1964).

8.1.7 Different model beams on a Pasternak foundation (Saito and Terasawa, 1980)

The governing equation of the rectangular beam, with shear deformation and rotatory inertia being ignored, is

$$\frac{1+v}{6} Gh^3 \frac{\partial^4 y}{\partial x^4} + \rho h \frac{\partial^2 y}{\partial t^2} + k_0 y + d \frac{\partial y}{\partial t} - G_0 \frac{\partial^2 y}{\partial x^2} = 0 \quad (8.9)$$

where h is height of the beam.

The governing equations of the rectangular beam, where shear deformation and rotatory inertia are incorporated, are

$$\begin{aligned} \frac{1+v}{6}Gh^3\frac{\partial^2\theta}{\partial x^2}-Gkh\left(\frac{\partial y}{\partial x}+\theta\right)-\frac{\rho h^3}{12}\frac{\partial^2\theta}{\partial t^2}=0 \\ \rho h\frac{\partial^2y}{\partial t^2}-Gkh\left(\frac{\partial^2y}{\partial x^2}+\frac{\partial\theta}{\partial x}\right)+k_0y+d\frac{\partial y}{\partial t}-G_0\frac{\partial^2y}{\partial x^2}=0 \end{aligned} \quad (8.10)$$

where θ is the bending slope and k is the shear coefficient.

8.1.8 'Generalized' foundation (Pasternak, 1954)

At the each point of the foundation the pressure p is proportional to the deflection y and the moment m is proportional to the angle of rotation

$$p = k_0y, \quad m = k_1 \frac{dy}{dn} \quad (8.11)$$

where n is any direction at a point in the plane of the foundation surface; k_0 and k_1 are the corresponding moduli of elasticity.

8.1.9 Reissner foundation (Reissner, 1958)

Assumptions

1. The in-plane stresses throughout the foundation layer are negligibly small.
2. The horizontal displacements at the upper and lower surfaces of the foundation layer are zero.

The relationship between the reaction of the foundation p and deflection y is

$$c_1y - c_2\nabla^2y = p - \frac{c_2}{c_1}\nabla^2p, \quad c_1 = \frac{E_0}{H}, \quad c_2 = \frac{HE_0}{3} \quad (8.12)$$

where E_0 and G_0 are the elastic constants of the foundation material, and H is the thickness of the foundation layer.

The case when Reissner's and Pasternak's models of foundation coincide, as well as the Vlasov foundation model (Vlasov and Leontiev, 1966) have been discussed by Kerr (1964).

8.2 UNIFORM BERNOULLI-EULER BEAMS ON AN ELASTIC WINKLER FOUNDATION

The differential equation of the transverse vibration of the beam resting on an elastic Winkler foundation without damping is

$$EI\frac{\partial^4y}{\partial x^4} + \rho A\frac{\partial^2y}{\partial t^2} + k_0y = 0 \quad (8.13)$$

Solution. Method of the separation of variables $y(x, t) = X(x)T(t)$, where $X(x)$ is a space-dependent function and $T(t)$ is a time-dependent function. A shape function $X(x)$ depends on the boundary conditions.

The space-dependent function $X(x)$ can be obtained from

$$X^{IV}(x) - k^4 X(x) = 0, \quad k^4 = \frac{m\omega^2 - k_0}{EI} = -4\alpha^4 \quad (8.14)$$

The natural frequencies are defined by the formula (Weaver, Timoshenko and Yaung, 1990; Hetenyi, 1958; Blevins, 1979)

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}} \sqrt{1 + \frac{k_0 l^4}{EI \lambda^4}} \quad (8.15)$$

Parameter λ corresponds to beams with the same boundary conditions but without an elastic foundation. The Winkler elastic foundation increases the frequency vibration.

Eigenfunction. The solutions of equation (6.2) may be presented in the following forms:

Case 1. The frequency parameter $k^4 > 0$.

The solutions of (8.2) are the same for $k_0 = 0$ and $k_0 \neq 0$. So, the elastic Winkler foundation has no effect on the mode shape vibration.

Case of long beams (Boitsov *et al.*, 1982)

$$X(kx) = e^{-\alpha x} (C_0 \cos \alpha x + C_1 \sin \alpha x) + e^{\alpha x} (C_2 \cos \alpha x + C_3 \sin \alpha x) \quad (8.4)$$

Case of short beams (especially for symmetric and antisymmetric forms)

$$X(kx) = C_0 \cosh \alpha x \cos \alpha x + C_1 \cosh \alpha x \sin \alpha x + C_2 \sinh \alpha x \sin \alpha x + C_3 \sinh \alpha x \cos \alpha x \quad (8.16)$$

Eigenfunction $X(x)$ may be presented in the form of Puzyrevsky functions

$$X(kx) = C_0 V_0(\alpha x) + C_1 V_1(\alpha x) + C_2 V_2(\alpha x) + C_3 V_3(\alpha x) \quad (8.17)$$

$$\begin{aligned} V_0 &= \cosh \alpha x \cos \alpha x & V_1 &= \frac{1}{\sqrt{2}} (\cosh \alpha x \sin \alpha x + \sinh \alpha x \cos \alpha x) \\ V_2 &= \sinh \alpha x \sin \alpha x & V_3 &= \frac{1}{\sqrt{2}} (\cosh \alpha x \sin \alpha x - \sinh \alpha x \cos \alpha x) \end{aligned} \quad (8.18)$$

8.2.1 Properties of Puzyrevsky functions

Puzyrevsky functions and their derivatives result in the diagonal matrix at $x = 0$.

$$\begin{array}{llll} V_0(0) = 1 & V'_0(0) = 0 & V''_0(0) = 0 & V'''_0(0) = 0 \\ V_1(0) = 0 & V'_1(0) = \sqrt{2}\alpha & V''_1(0) = 0 & V'''_1(0) = 0 \\ V_2(0) = 0 & V'_2(0) = 0 & V''_2(0) = 2\alpha^2 & V'''_2(0) = 0 \\ V_3(0) = 0 & V'_3(0) = 0 & V''_3(0) = 0 & V'''_3(0) = 2\sqrt{2}\alpha^3 \end{array} \quad (8.19)$$

Derivatives of Puzrevsky Functions

$$\begin{aligned} V'_3(\alpha x) &= \sqrt{2}\alpha V_2(\alpha x); & V'_2(\alpha x) &= \sqrt{2}\alpha V_1(\alpha x) \\ V'_1(\alpha x) &= \sqrt{2}\alpha V_0(\alpha x); & V'_0(\alpha x) &= -\sqrt{2}\alpha V_3(\alpha x) \end{aligned}$$

Case 2. The frequency parameter $k^4 < 0$.

The solution of (8.2) is

$$X = A \sin \frac{kx}{\sqrt{2}} \sinh \frac{kx}{\sqrt{2}} + B \sin \frac{kx}{\sqrt{2}} \cosh \frac{kx}{\sqrt{2}} + C \cos \frac{kx}{\sqrt{2}} \sinh \frac{kx}{\sqrt{2}} + D \cos \frac{kx}{\sqrt{2}} \cosh \frac{kx}{\sqrt{2}} \quad (8.20)$$

which is different from expressions (8.4) and (8.5) (Wang, 1991).

8.2.2 Beams on linear inertial foundation

The beam length l and mass per unit m rest on an elastic foundation. A linear inertial foundation is a two-way communication one. The model of the foundation represents separate rods with parameters: modulus E_F , cross-sectional area $A_F = b \times 1$, and density ρ_F ; the length of the rods is l_0 (Fig. 8.1) (Bondar', 1971).

Reaction of the rods

$$q_0 = -E_F A_F \left. \frac{\partial u}{\partial z} \right|_{z=l_0}$$

where u is the longitudinal displacement of the rod.

Differential equations

(a) Longitudinal vibration of the rods

$$\frac{\partial^2 u}{\partial t^2} = a^2 \frac{\partial^2 u}{\partial z^2} \quad (8.21)$$

$$\text{where } a^2 = \frac{E_F A_F}{m_F}, \quad A_F = b \times 1 \quad m_F = \rho_F A_F$$

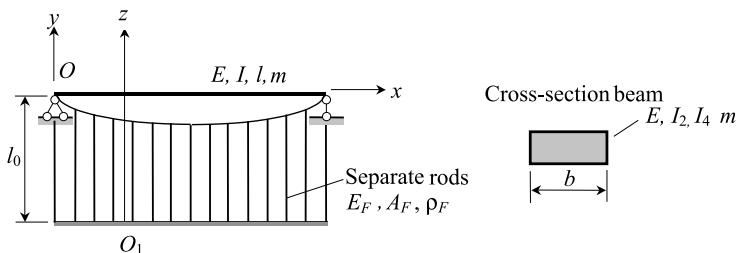

FIGURE 8.1. Mechanical model of elastic foundation. System coordinates: for beam xOy ; for rods O_1z .

(b) Transverse vibration of the beam

$$EI_2 \frac{\partial^4 y}{\partial x^4} + m \frac{\partial^2 y}{\partial t^2} + E_F A_F \frac{\partial u}{\partial z} \Big|_{z=l_0} = 0 \quad (8.22)$$

where the moment of inertia of the cross-sectional area of order n is

$$I_n = \int_{(A)} z^n dA$$

where z is a distance from the neutral axis. For a rectangular cross-section, $b \times h$:

$$I_2 = bh^3/12, \quad I_4 = bh^5/80$$

The differential equation for the mode shape of vibration is

$$X'''' + \left(C \frac{\omega}{a} \cot \frac{\omega}{a} l_0 - b^2 \omega^2 \right) X = 0 \quad (8.23)$$

where

$$C = \frac{E_F A_F}{EI_2}, \quad b^2 = \frac{m}{EI_2}$$

The frequency equation may be presented in the form

$$\left(\frac{n\pi}{l}\right)^4 + C \frac{\omega}{a} \cot \frac{\omega}{a} l_0 - b^2 \omega^2 = 0 \quad (8.24)$$

or

$$\left(\frac{n\pi}{l}\right)^4 \tan \gamma = \left(\frac{ab\gamma}{l_0}\right)^2 \tan \gamma - \frac{C\gamma}{l_0} \quad (8.24a)$$

$$\text{where } \gamma = \frac{\omega}{a} l_0, \omega = \gamma \frac{a}{l_0} = \frac{\gamma}{l_0} \sqrt{\frac{E_F}{\rho_F}}.$$

This equation takes into account the bending stiffness of the beam and the elastic foundation. The fundamental natural frequency of vibration

$$\omega = \frac{\gamma}{l_0} \sqrt{\frac{E_F}{\rho_F}} \quad (8.25)$$

where γ is the minimal root of the frequency equation (8.24). For soil of average density the length of the rods, l_0 , approximately equals $5l$. For the condition $l_0 = 5l$, displacement of the bottom ends of the rods makes up 2.5% of the displacement of the beam. For more details see Section 14.4.

Special cases

1. *No-foundation condition.* In this case, $E_F = 0$, then $C/a = 0$ and the frequency equation of the beam becomes

$$\left(\frac{n\pi}{l}\right)^4 - b^2 \omega^2 = 0$$

The frequency of the transverse vibration of the beam is

$$\omega_n = \left(\frac{n\pi}{l}\right)^2 \sqrt{\frac{EI_2}{m}}, \quad (n = 1, 2, 3, \dots)$$

2. No-beam condition. In this case $EI_2 = 0$, then $b = \infty$, $C = \infty$ and the frequency equation of the clamped-free rod becomes

$$\tan \gamma = \infty, \quad \gamma = \frac{i\pi}{2}, \quad i = 1, 3, 5, \dots$$

The frequency of the longitudinal vibration of the clamped-free rod is

$$\omega_{\text{cl-fr}} = \frac{i\pi}{2l_0} \sqrt{\frac{E_F}{m_F}}, \quad i = 1, 3, 5, \dots$$

3. Beam is absolutely rigid. $EI_2 = \infty$ then $b = 0$, $C = 0$ and the frequency equation becomes $\tan \gamma = 0$, $y = i\pi$, $i = 1, 2, 3, \dots$. The frequency of the longitudinal vibration of the clamped-clamped rod is

$$\omega_{\text{cl-cl}} = \frac{i\pi}{l_0} \sqrt{\frac{E_F}{m_F}}, \quad i = 1, 2, 3, \dots$$

For the fundamental mode ($i = 1$) the frequency of vibration ω of the system's 'beam-inertial foundation' satisfies condition

$$\omega_{\text{cl-fr}} \leq \omega \leq \omega_{\text{cl-cl}}$$

8.3 PINNED-PINNED BEAM UNDER COMPRESSIVE LOAD

The design diagram of a pinned-pinned uniform beam on an elastic foundation with compressive load N is presented in Fig. 8.2. The parameters of the elastic foundation are $k_{\text{slope}} = D_0$, $k_{\text{tr}} = k_0$ and k_{tilt} (Nielsen, 1991).

8.3.1 Bernoulli-Euler beam theory

Winkler foundation. The differential equation of the transverse vibration is

$$EIy^{IV} + Ny'' + k_{\text{tr}}y + m\ddot{y} = 0 \quad (8.26)$$

FIGURE 8.2. Beam on an elastic foundation.

where y denotes the transverse displacement of the beam axis at position x and time t . The elastic foundation does not change the boundary condition.

Frequency of vibration

$$\omega_n = \frac{n^2\pi^2}{l^2} \sqrt{\frac{EI}{m}} \sqrt{1 - \frac{Nl^2}{EIn^2\pi^2} + \frac{k_{tr}l^4}{EIn^4\pi^4}}, \quad n = 1, 2, \dots \quad (8.27)$$

Pasternak foundation. The differential equation of the transverse vibration is

$$EIy'''' + (N - k_{slope})y'' + k_{tr}y + m\ddot{y} = 0 \quad (8.28)$$

The natural frequency of vibration is

$$\omega_n = \frac{n^2\pi^2}{l^2} \sqrt{\frac{EI}{m}} \sqrt{1 - \frac{(N - k_{slope})l^2}{EIn^2\pi^2} + \frac{k_{tr}l^4}{EIn^4\pi^4}} \quad (8.29)$$

The elastic foundation leads to the increment of the eigenfrequencies, whereas the compressive force leads to the decrement of the eigenfrequencies.

8.3.2 Rayleigh–Timoshenko beam theory

The differential equations of the transverse vibration for an undamped beam are

$$\begin{aligned} kGA(y' + \phi)' &= m\ddot{y} + k_{tr}y + Ny'' \\ EI\phi'' - kGA(y' + \phi) + k_{slope}y' &= mr^2\ddot{\phi} + k_{tilt}\phi \end{aligned} \quad (8.30)$$

where $y(x, t)$ and $\phi(x, t)$ denote the transverse displacement of the beam axis and the transverse rotation (tilting) of the beam cross-section at position x and time t ; I and r are the moment of inertia and the radius of gyration of the cross-section with respect to the z -axis (Lunden and Akesson, 1983).

Solution

$$y = A_1 \sin \frac{n\pi x}{l} \exp(i\omega t), \quad \phi = A_2 \cos \frac{n\pi x}{l} \exp(i\omega t)$$

The eigenvalues of the pinned–pinned beam are

$$\begin{bmatrix} (N - kGA)\left(\frac{n\pi}{l}\right)^2 + m\omega^2 - k_{tr} & -kGA \frac{n\pi}{l} \\ -(kGA - k_{slope})\frac{n\pi}{l} & mr\omega^2 - kGA - k_{tilt} - EI\left(\frac{n\pi}{l}\right)^2 \end{bmatrix} = 0 \quad (8.31)$$

The frequency equation may be presented in the form

$$\omega_n^2 = \frac{kGA}{2mr^2} \left[B_1 \pm \sqrt{B_1^2 - \frac{4r^2 B_2}{kGA}} \right] \quad (8.32)$$

$$B_1 = 1 + \frac{k_{\text{tilt}} + EI\mu_n^2 + r^2 k_{\text{tr}}}{kGA} + r^2 \left(1 - \frac{N}{kGA}\right) \mu_n^2 \quad \mu_n = \frac{n\pi}{l}$$

$$B_2 = k_{\text{tr}} \left(1 + \frac{k_{\text{tilt}} + EI\mu_n^2}{kGA}\right) + \left(1 - \frac{N}{kGA}\right) (k_{\text{tilt}} + EI\mu_n^2) \mu_n^2 + (k_{\text{slope}} - N) \mu_n^2$$

It may occur that the minimum eigenfrequency does not correspond to the simplest mode of vibration ($n = 1$).

8.4 A STEPPED BERNOULLI-EULER BEAM SUBJECTED TO AN AXIAL FORCE AND EMBEDDED IN A NON-HOMOGENEOUS WINKLER FOUNDATION

A design diagram of a stepped beam is presented in Fig. 8.3. Boundary conditions are not shown. The elastic foundation is non-uniform with translational stiffness coefficients k_0 and k_1 . The exact fundamental eigenfrequencies for a beam with different boundary conditions, beam parameters, load and foundation are presented in Tables 8.1 and 8.2. The method of separation of variables is applied (Filipich *et al.*, 1988).

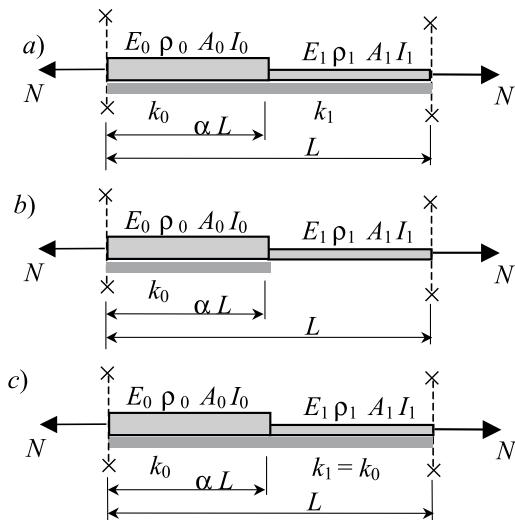

FIGURE 8.3. Stepped beam embedded in a non-homogeneous foundation.

The dimensionless parameters of the system are

$$\begin{aligned} w_0^2 &= \frac{k_0 L^4}{E_0 I_0}, \quad w_1^2 = \frac{k_1 L^4}{E_0 I_0}, \quad \beta = \frac{E_1 I_1}{E_0 I_0}, \quad \gamma = \frac{\rho_1 A_1}{\rho_0 A_0} \\ p^2 &= \frac{NL^2}{E_0 I_0} (\geq 0), \quad \varepsilon = \left(\frac{w_1}{w_0} \right)^2 = \frac{k_1}{k_0}, \quad \Omega^2 = \omega^2 L^4 \frac{\rho_0 A_0}{E_0 I_0} \end{aligned}$$

8.4.1 The stepped beam is partially embedded in a Winkler foundation (Fig. 8.3(b))

In this case $k_1 = 0$ and $w_0 = \varepsilon = 0$. The fundamental eigenvalues, Ω_1 , for $\alpha = 0.5$; $\beta = 0.512$; $\gamma = 0.8$ and $w_0^2 = 25$ are presented in Table 8.1.

TABLE 8.1. One-span stepped beam partially embedded in a Winkler foundation: Fundamental frequency vibration for beams with different boundary conditions and axial force

FIGURE 8.4. (a) Infinite beam with lumped mass on elastic foundation (b) Corresponding frequency spectrum.

8.5 INFINITE UNIFORM BERNOULLI-EULER BEAM WITH A LUMPED MASS ON AN ELASTIC WINKLER FOUNDATION

An infinite uniform Bernoulli–Euler beam with a distributed mass m and lumped mass M on an elastic Winkler foundation with modulus elasticity k is presented in Fig. 8.4(a).

The spectrum of this system is mixed (discrete and continuous) and is presented in Fig. 8.4(b). The discrete frequency ω_M is a real root of the characteristics equation (Bolotin, 1978)

$$\frac{\omega^2 M}{8EI} = \left(\frac{k - m\omega^2}{4E} \right)^{3/4} \quad (8.33)$$

The distributed spectrum begins in the frequency $\omega_0 = \sqrt{\frac{k}{m}}$.

CHAPTER 9

BERNOULLI-EULER MULTISPAN BEAMS

This chapter contains analytical and numerical results for Bernoulli–Euler multispan beams on rigid and/or the elastic supports.

NOTATION

A	Cross-sectional area of the beam
E	Modulus of elasticity of the beam material
EI	Bending stiffness
i	Bending stiffness per unit length, $i = EI/l$
I	Moment of inertia of a cross-sectional area of the beam
k	Frequency parameter, $k^4 = \frac{m\omega^2}{EI}$
l	Length of the beam
M	Bending moment, amplitude of harmonic moment
r_{ik}	Unit reaction of the slope-deflection method
S, T, U, V	Krylov–Duncan functions
t	Time
x	Spatial coordinate
x, y, z	Cartesian coordinates
$X(x)$	Mode shape
$y(x, t), w$	Lateral displacement of the beam
Z	Unknown of the slope-deflection method
λ	Frequency parameter, $\lambda^2 = k^2 l^2$
ρ, m	Density of material and mass per unit length of beam, $m = \rho A$
$\phi(\lambda), \psi(\lambda)$	Zal'tsberg functions
ω	Natural frequency of free transverse vibration

9.1 TWO-SPAN UNIFORM BEAMS

The eigenvalue problem for uniform multispan beams with a distributed mass and with/without lumped masses may be studied by using different classical methods. The

most effective among these methods are the slope-deflection method, which uses specific functions (see Chapter 4), and the force method in the form of three moment equations. These methods lead to a governing equation for eigenvalues in exact analytical form.

9.1.1 Beams with equal spans

Natural frequencies of vibration are

$$\omega_i = \frac{\lambda_i^2}{l^2} \sqrt{\frac{EI}{m}} \quad (9.1)$$

The first five frequency parameters λ for two-span beams with classical boundary conditions are presented in Table 9.1. One-span beams with overhangs are considered in Chapter 7.2 and Table 7.11.

Exact values of the frequency parameter λ for the fundamental mode of vibration of two-span uniform beams with equal spans, are presented in Table 9.2 (Gorman, 1974; Kameswara Rao, 1990).

9.1.2 Two-span beam with an elastic support at the middle span

The symmetrical beam with an elastic support is presented in Fig. 9.1(a). The frequency equation may be presented in different forms.

Symmetric vibration (Anan'ev, 1946; Boitsov et al., 1982). In term of Hohenemser-Prager functions

$$k^* = -\lambda^3 \frac{C(\lambda)}{B(\lambda)} \quad (9.2)$$

In term of Krylov functions

$$k^* = -\lambda^3 \frac{S^2(\lambda) - U^2(\lambda)}{T(\lambda)U(\lambda) - S(\lambda)V(\lambda)} \quad (9.2a)$$

In explicit form

$$k^* = -\lambda^3 \frac{2 \cosh \lambda \cos \lambda}{\cosh \lambda \sin \lambda - \sinh \lambda \cos \lambda} \quad (9.2b)$$

where the dimensionless stiffness parameter $k^* = \frac{kl^3}{2EI}$.

The natural frequency of vibration is

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$$

The roots of the frequency equation in terms of dimensionless parameter k^* are shown in Fig. 9.1(b).

Eigenfunctions for the given system and for the pinned-clamped beam are the same.

Antisymmetric vibration. The frequency equation is

$$S_1(\lambda) = 0, \quad \lambda_1 = \pi, \quad \lambda_2 = 2\pi, \quad \lambda_3 = 3\pi, \dots$$

where S_1 is the Hohenemser-Prager function (Section 4.6).

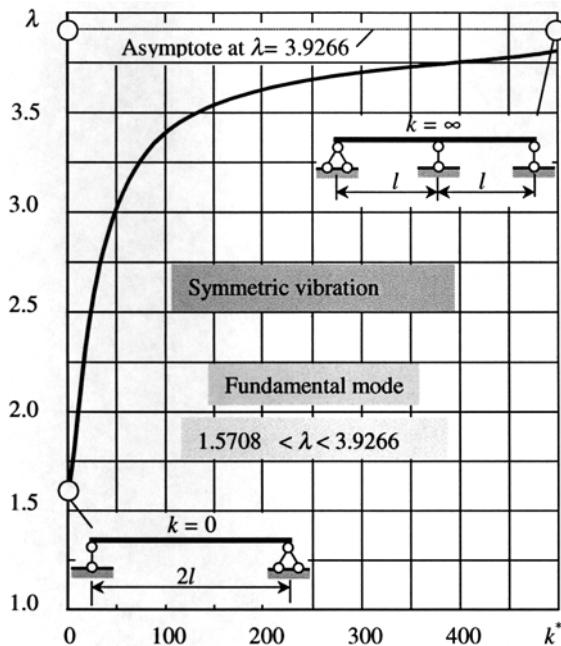

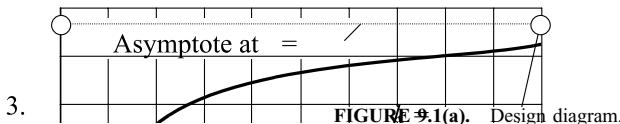

Eigenfunctions for the given system and for the pinned-pinned beam are the same.

9.1.3 Beams with different spans

Tables 9.3(a), (b), (c) contain the frequency equations and mode-shape expressions for ten types of two-span uniform beams with classical boundary conditions (Gorman, 1974; Kameswara Rao, 1990). Dimensionless parameters are

$$\mu = \frac{l_1}{L}, \quad v = \frac{l_2}{L} = 1 - \mu$$

$$\xi_1 = \frac{x_1}{l_1}, \quad \xi_2 = \frac{x_2}{l_2}$$

$$M_{1,2} = \cos \lambda \mu \sinh \lambda \mu \mp \sin \lambda \mu \cosh \lambda \mu$$

$$N_{1,2} = \cos \lambda v \sinh \lambda v \mp \sin \lambda v \cosh \lambda v$$

The frequency parameter is $\lambda_n^4 = \frac{\rho A L^4}{EI} \omega_n^2$, where $l_1 + l_2 = L$.

Special cases. Two-span beams reduce to one-span beams in the two special cases.

1. $l_1 = 0 (\mu = 0, v = 1)$.
2. $l_2 = 0 (\mu = 1, v = 0)$.

The types of the given beams and beams that correspond to special cases are presented in Table 9.4.

The related data for special cases are contained in Tables 5.3 and 5.4.

9.1.4 Numerical results

Figures 9.2(a)–(j) give frequency parameter values, λ , for the first three modes of vibration as a function of intermediate support spacing, μ , for two-span uniform beams with different boundary conditions (Gorman, 1974; Kameswara Rao, 1990).

Guided-pinned-XX beam. A two-span uniform beam with intermediate support is presented in Fig. 9.3. The beam has guided support at the left-hand end and specific XX support at the right-hand end. The boundary condition, shown as XX, is a clamped support, or guided, or pinned, or free end.

Values of fundamental parameters λ for guided-pinned-XX beams for various values of intermediate support spacing, $\mu = l_1/L$, and end conditions, XX, are presented in Table 9.5. This table also presents the location of the intermediate support, which leads to the maximum value of the frequency parameter.

The first row in the table may be used for determination of frequency parameters for single-span beams with the following boundary conditions: clamped-free, clamped-guided, clamped-pinned and clamped-clamped, respectively (see Tables 5.3 and 5.4).

The last row in Table 9.5 may be used for calculation of single-span guided-pinned and guided-clamped beams.

9.2 NON-UNIFORM BEAMS

9.2.1 Exact methods

Two classical methods are presented.

Slope and deflection method. The slope and deflection method is used for calculation of continuous beams and frames (Flugge, 1962; Darkov, 1989).

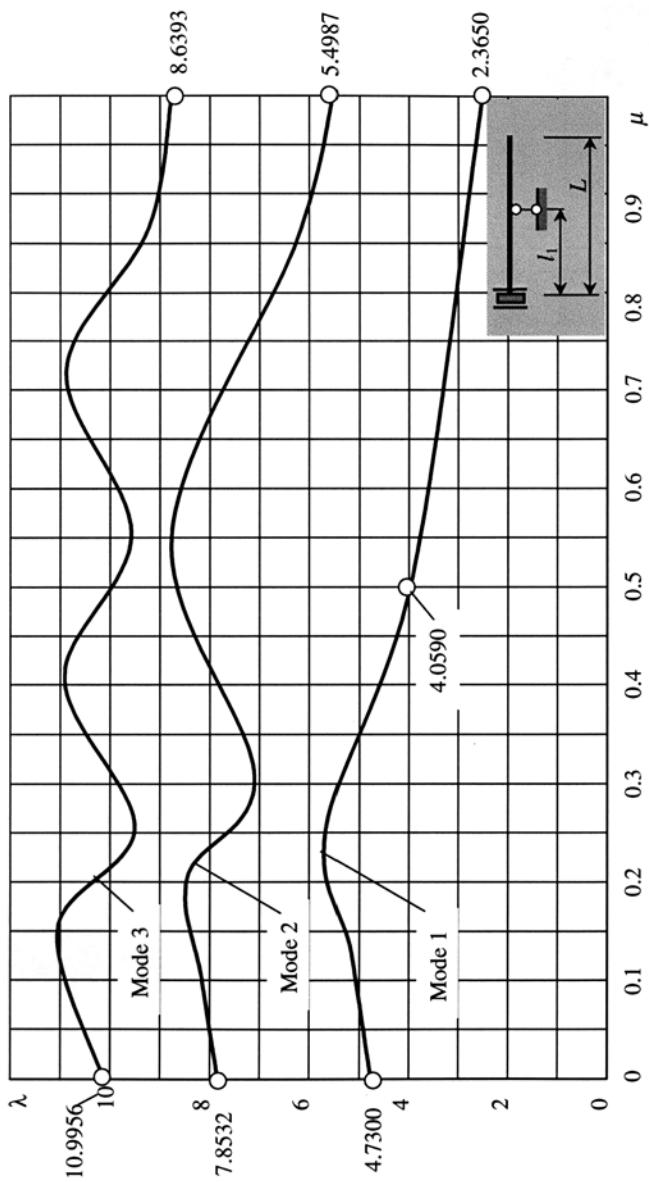

FIGURE 9.2(j). Guided-pinned-clamped beam.

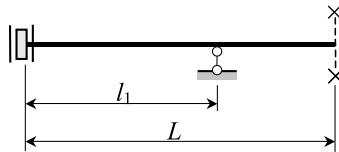

FIGURE 9.3. Design diagram of guided-pinned-XX beams. The XX boundary condition is a free, or guided, or pinned, or clamped end.

Assumptions

1. The strains and displacements due to normal and shearing forces will be neglected.
2. The difference in length between the original member and the chord of the elastic line is practically non-existent.

Unknowns. The unknowns of this method represent the deflection and angles of twist of various joints induced by bending moments. The total number of unknowns is

$$n = n_d + n_t \quad (9.3)$$

where n_t is a number of rigid joints of a frame;

n_d is a number of independent deflections of the joints of a frame.

The number of unknown angles of twist is equal to the number of the rigid joints of the structure.

0.55	$\lambda_{\max} = 2.3650$	3.0991	3.6582	3.7461
0.60	2.3416	2.9956	3.4247	3.5128
0.65	2.2725	2.8705	3.2229	3.2971
0.70	2.1741	2.7479	3.0482	3.1102
0.75	2.0631	2.6379	2.8960	2.9469
0.80	1.9510	2.5447	2.7627	2.8030
0.85	1.8438	2.4696	2.6453	2.6752
0.90	1.7444	2.4136	2.5411	2.5610
0.95	1.6534	2.3778	2.4482	2.4581
1.00	1.5708	2.3650	2.3650	2.3650

The number of independent joint deflections is equal to the degree of instability of the system obtained by the introduction of hinges at all of the rigid joints and supports of the original structure.

Conjugate redundant system. In order to obtain the conjugate redundant system (primary system), the additional constraints introduced must prevent the rotation of all rigid joints as well as the independent deflections of these joints.

Canonical equation. The equations of the slope and deflection method negate the existence of reactive moments and forces developed by the imaginary constraints of the conjugate system of redundant beams. According to the reaction reciprocal theorem, $r_{ik} = r_{ki}$ (Section 2.1).

The canonical equation may be written as

$$\begin{aligned} r_{11}Z_1 + r_{12}Z_2 + \cdots + r_{1n}Z_n + R_{1p} &= 0 \\ r_{21}Z_1 + r_{22}Z_2 + \cdots + r_{2n}Z_n + R_{2p} &= 0 \\ \cdots \\ r_{n1}Z_1 + r_{n2}Z_2 + \cdots + r_{nn}Z_n + R_{np} &= 0 \end{aligned} \quad (9.4)$$

Coefficient r_{ik} is the amplitude of the dynamical reaction (moment or force) induced in the imaginary support i due to harmonic deflection (angle or linear) of the k th constraint. In the case of the eigenproblem, the free terms $R_{ip} = 0$. So the frequency equation is

$$D = \begin{vmatrix} r_{11} & r_{12} & \cdots & r_{1n} \\ r_{21} & r_{22} & \cdots & r_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ r_{n1} & r_{n2} & \cdots & r_{nn} \end{vmatrix} = 0 \quad (9.5)$$

Example. Statically indeterminant framed systems A , B and C are presented in Fig. 9.4. The uniformly distributed masses are m_1 for the cross bar and m_2 for the vertical element. Show the conjugate system (CS) and determine the coefficients of the unknowns in the slope and deflection method for given systems A , B and C .

Solution

Analysis of the structures. The systems A , B and C have one rigid joint. Systems A and B do not have a linear deflection, whereas system C has a linear deflection in the horizontal direction. Consequently, frames A and B have one unknown of the deflection-slope method, namely the angle of the twist of the rigid joint; frame C has two unknowns, namely the angle of the twist and deflection of the rigid joint.

Conjugate system. Conjugate system for systems A and B : additional constraint 1 opposes the rotation of the rigid joint included in the original system.

Conjugate system for systems C : additional constraints 1 and 2 oppose the rotation and deflection of the joint included in the original system.

The free-body diagram for r_{11} and r_{12} is the rigid joint; the free-body diagram for r_{21} and r_{22} is the cross bar. The dynamic reactions at the ends of the members and forces depend on the type of displacement (linear or angular), and on the mass distribution along the frame element, such as distributed, or lumped masses. These cases are presented in

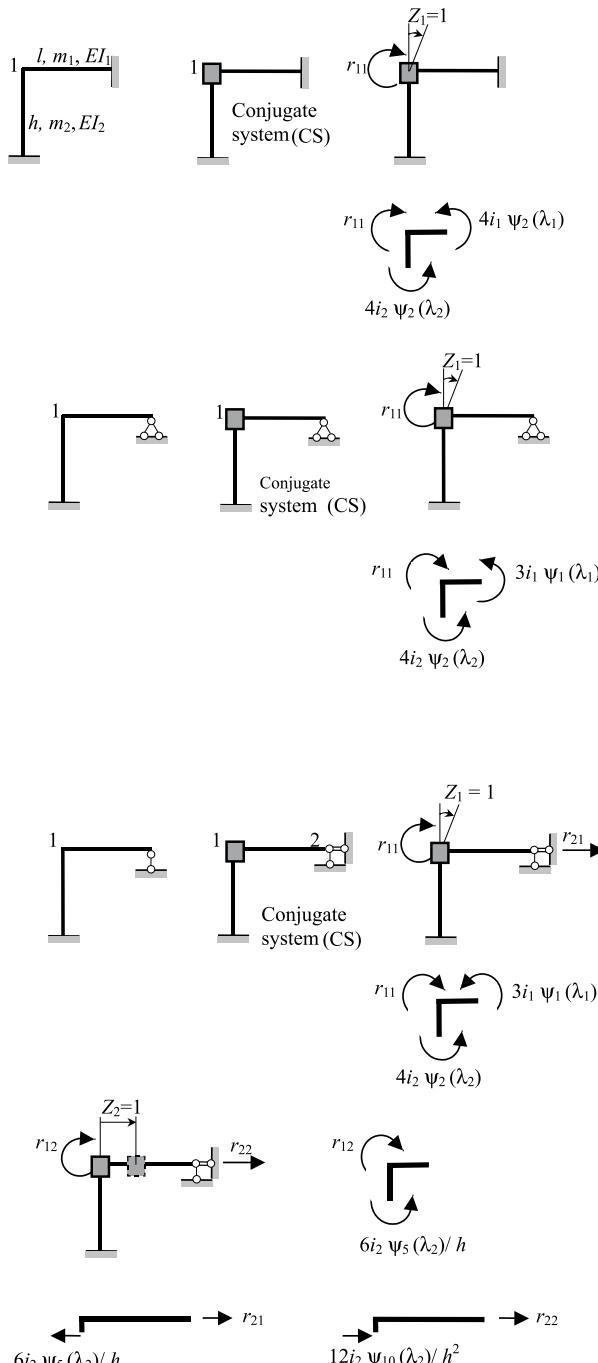

FIGURE 9.4. Redundant frames, primary systems and free body diagrams.

TABLE 9.6. Design diagrams of a single element of a frame

	Massless elements with one lumped mass	Elements with distributed mass	Elements with distributed and one lumped mass
			
Functions, related materials	Table 4.3	Krylov-Duncan: Section 4.1 Zal'tsberg: Section 9.5 Smirnov: Table 4.6 Bolotin: Table 4.7 Hohenemser-Prager: Table 4.9, Section 4.5	Kiselev: Table 4.8

Table 9.6. The corresponding special functions are discussed in Chapter 4. We use Smirnov's functions. The unit reactions are

$$\text{System } A: \quad r_{11} = 4i_1\psi_2(\lambda_1) + 4i_2\psi_2(\lambda_2)$$

$$\text{System } B: \quad r_{11} = 3i_1\psi_1(\lambda_1) + 4i_2\psi_2(\lambda_2)$$

$$\text{System } C: \quad r_{11} = 3i_1\psi_1(\lambda_1) + 4i_2\psi_2(\lambda_2)$$

$$r_{12} = r_{21} = \frac{6i_2}{h}\psi_5(\lambda_2)$$

$$r_{22} = \frac{12i_2}{h^2}\psi_{10}(\lambda_2)$$

Note the indices with i and λ denote the element (1 for a horizontal element and 2 for a vertical one); the index with ψ denotes the number of functions according to Table 4.4.

The bending stiffness per unit length is

$$i_1 = \frac{EI_1}{l}, \quad i_2 = \frac{EI_2}{h}$$

The frequency parameters λ_1 and λ_2 are

$$\lambda_1 = l_1 \sqrt[4]{\frac{m_1 \omega^2}{EI_1}}; \quad \lambda_2 = l^2 \sqrt[4]{\frac{m_2 \omega^2}{EI_2}}$$

Let the base eigenvalue be

$$\lambda_1 = l_1 \sqrt[4]{\frac{m_1 \omega^2}{EI_1}} = \lambda, \text{ then } \lambda_2 = \lambda \frac{l_2}{l_1} \sqrt[4]{\frac{m_2 EI_1}{m_1 EI_2}}.$$

The frequency equation should be written in the form of (9.5).

Table 9.6 presents different types of design diagram of the elements and the corresponding functions that could be applied for dynamic calculation of a structure with these elements.

Three-moment equation (Kiselev, 1980; Filippov, 1970). This method is convenient to use for multispan beams with a different stiffness for each span. The three-moment equation establishes a relationship between the moments on the three series of beam supports. The notation of the spans and supports is presented in Fig. 5.6. The canonical form of the equations may be written in the form of (5.7) or (5.8).

The system of equations ((5.7) or (5.8)) has a non-trivial solution if and only if the determinant obtained from the coefficients at the support moments is zero. This condition leads to the frequency of vibration.

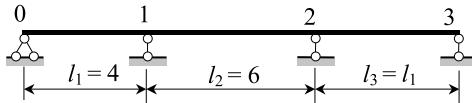

FIGURE 9.5. Design diagram of the uniform three-span symmetric beam.

Example. Derive the frequency equation of the symmetric vibration of the uniform three-span beam shown in Fig. 9.5. Apply the three-moment equation.

Solution. The equation of the symmetrical vibration is

$$\frac{l_1}{6EI_1} f_2(\lambda_1) M_0 + 2 \left[\frac{l_1}{6EI_1} f_1(\lambda_1) + \frac{l_2}{6EI_2} f_1(\lambda_2) \right] M_1 + \frac{l_2}{6EI_2} f_2(\lambda_2) M_2 = 0$$

Because of symmetry $M_1 = M_2$; $M_0 = 0$, so

$$2 \left[\frac{l_1}{6EI_1} f_1(\lambda_1) + \frac{l_2}{6EI_2} f_1(\lambda_2) \right] M_1 + \frac{l_2}{6EI_2} f_2(\lambda_2) M_2 = 0$$

Since $EI_1 = EI_2 = EI$, so

$$2 \left[\frac{4}{6EI} f_1(\lambda_1) + \frac{6}{6EI} f_1(\lambda_2) \right] M_1 + \frac{6}{6EI} f_2(\lambda_2) M_2 = 0$$

After reducing by $2/6EI$ the previous equation becomes

$$4f_1(\lambda_1) + 6f_1(\lambda_2) + 3f_2(\lambda_2) = 0$$

The relationship between λ_1 and λ_2 is $\frac{\lambda_2}{\lambda_1} = \frac{l_2}{l_1} = 1.5$. This leads to

$$4f_1(\lambda_1) + 6f_1(1.5\lambda_1) + 3f_2(1.5\lambda_1) = 0$$

Consequently, the frequency equation in terms of $\lambda_1 = \lambda$ is (Kiselev, 1980)

$$4 \times \frac{3}{2} \times \frac{\cosh \lambda \sin \lambda - \sinh \lambda \sin \lambda}{\lambda \sinh \lambda \sin \lambda} + 6 \times \frac{3}{2} \times \frac{\cosh 1.5\lambda \sin 1.5\lambda - \sinh 1.5\lambda \sin 1.5\lambda}{\lambda \sinh 1.5\lambda \sin 1.5\lambda} + 3 \times 3 \times \frac{\sinh 1.5\lambda - \sin 1.5\lambda}{\lambda \sinh 1.5\lambda \sin 1.5\lambda} = 0$$

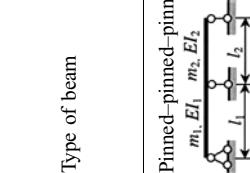

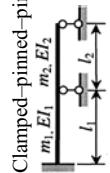

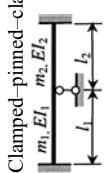

If the uniform beam has uniform spacing, then a three-moment equation may be presented in terms of Krylov-Duncan functions

$$V_n M_{n-1} + 2(T_n U_n - S_n V_n) M_n + V_{n+1} M_{n+1} = 0$$

9.2.2 Non-uniform two-span beams

Frequency equation for non-uniform two-span beams by using special functions (slope and deflection method) are presented in Table 9.7.

TABLE 9.7 Non-uniformly two-span beams: Frequency equations in different forms (slope and deflection method)

Type of beam		Frequency equation	Frequency equation
Pinned-pinned-pinned		$\frac{3EI_1}{l_1} \psi_1(u_1) + \frac{3EI_2}{l_2} \psi_1(u_2) = 0$ (Smirnov's functions (Table 4.6) $(\lambda = kl, \omega^2 = k^4 EI/m)$	$\frac{3EI_1}{l_1} \frac{\lambda(T_1^2 - V_1^2)}{3(T_1 U_1 - S_1 V_1)} + \frac{3EI_2}{l_2} \frac{\lambda(T_2^2 - V_2^2)}{3(T_2 U_2 - S_2 V_2)} = 0$ (Krylov's functions (Section 4.1) (Prokof'ev and Smirnov, 1948)
Clamped-pinned-pinned		$\frac{4EI_1}{l_1} \psi_2(u_1) + \frac{3EI_2}{l_2} \psi_1(u_2) = 0$ (Smirnov's functions (Table 4.6) $(\lambda = kl, \omega^2 = k^4 EI/m)$	$\frac{4EI_1}{l_1} \frac{\lambda(T_1 U_1 - S_1 V_1)}{4(U_1^2 - T_1 V_1)} + \frac{3EI_2}{l_2} \frac{\lambda(T_2^2 - V_2^2)}{3(T_2 U_2 - S_2 V_2)} = 0$ (Bolotin's functions (Section 4.3) $(k = m\omega^2 \beta^3)$ (Bolotin, 1978)
Clamped-pinned-clamped		$\frac{4EI_1}{l_1} \psi_2(u_1) + \frac{4EI_2}{l_2} \psi_2(u_2) = 0$ (Smirnov's functions (Table 4.6) $(\lambda = kl, \omega^2 = k^4 EI/m)$	$\frac{4EI_1}{l_1} \frac{\lambda(T_1 U_1 - S_1 V_1)}{4(U_1^2 - T_1 V_1)} + \frac{4EI_2}{l_2} \frac{\lambda(T_2 U_2 - S_2 V_2)}{4(U_2^2 - T_2 V_2)} = 0$ (Krylov's functions (Section 4.1) (Prokof'ev and Smirnov, 1948)

1. The conjugate system contains the imaginary fixed joint at the intermediate support. This additional restriction prevents rotation.

2. The basic unknown of the slope and deflection method is the angle of rotation of the fixed joint.

3. The canonical equation is $r_{11} Z_1 = 0$.4. The frequency equation is $r_{11} = 0$, where r_{11} is the reactive moment at the fixed joint due to rotation of the fixed joint through an angle equal to unity.

9.3 THREE-SPAN UNIFORM SYMMETRIC BEAMS

9.3.1 Beam on rigid supports

A symmetric three-span continuous beam and its half-beam for symmetric and antisymmetric vibration are shown in Figs. 9.6(a), 9.6(b), and 9.6(c), respectively.

The natural frequency of vibration is

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$$

where $l = l_1 + \frac{l_2}{2}$.

The frequency equation for symmetric vibration in terms of Hohenemser-Prager functions is (Anan'ev, 1946)

$$C[\lambda(1 - l^*)B(\lambda l^*) + A[\lambda(1 - l^*)]S_1(\lambda l^*) = 0 \quad (9.6)$$

where the dimensionless parameter $l^* = \frac{l_1}{l}$

The frequency parameter λ for the fundamental mode of vibration is presented in Fig. 9.7(d).

The frequency equation for antisymmetric vibration in terms of the Hohenemser-Prager functions is

$$B[\lambda(1 - l^*)]S_1(\lambda l^*) + S_1[\lambda(1 - l^*)]B(\lambda l^*) = 0 \quad (9.7)$$

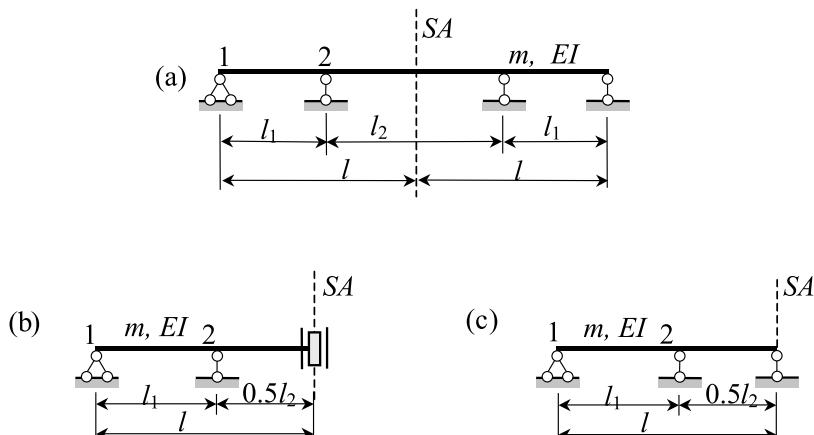

FIGURE 9.6. Three-span uniform beam on rigid supports. SA = axis of symmetry.

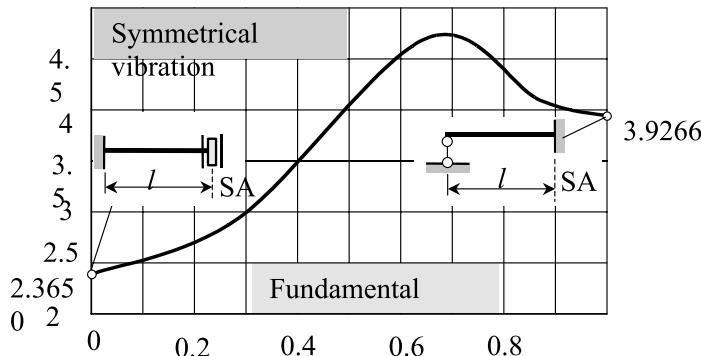

FIGURE 9.7. Three-span uniform symmetric continuous beam: parameter λ as a function of $l^* = l_1/l$ for fundamental mode of vibration.

Special cases. Limiting cases for $l_1 = 0$ and $l_2 = 0$ transfer the given system into a new system (Table 9.8).

TABLE 9.8. Transformation of two-span beams: limiting cases of the span length and corresponding frequency parameters

	$l_1 = 0$ ($l = 0.5l_2$)	$l_2 = 0$ ($l = l_1$)
Symmetric vibration	Clamped-guided $\lambda = 2.3650; 5.49878; 9.63938\dots$ $0.25\pi(4n - 1)$	Pinned-clamped $\lambda = 3.9266; 7.06858; 10.2101,\dots$ $0.25\pi(4n + 1)$
Antisymmetric vibration	Clamped-pinned $\lambda = 3.9266; 7.06858; 10.2101,\dots$ $0.25\pi(4n + 1)$	Pinned-clamped $\lambda = 3.9266; 7.06858; 10.2101,\dots$ $0.25\pi(4n + 1)$

9.3.2 Beam with elastic end supports

A symmetric three-span continuous beam and its half-beam for symmetric and antisymmetric vibrations are shown in Fig. 9.8(a).

The natural frequency of vibration is

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}},$$

where $l = l_1 + \frac{l_2}{2}$.

The frequency equation for symmetric vibration in terms of Hohenemser-Prager functions is (Anan'ev, 1946)

$$\frac{k^3}{EI} = -\lambda^3 \frac{C[\lambda(1 - l^*)]E(\lambda l^*) - A[\lambda(1 - l^*)]B(\lambda l^*)}{C[\lambda(1 - l^*)]B(\lambda l^*) + A[\lambda(1 - l^*)]S_1(\lambda l^*)} \quad (9.8)$$

where the dimensionless geometry parameter $l^* = \frac{l_1}{l}$.

The frequency parameter, λ , for the fundamental mode of vibration is presented in Fig. 9.8.

Special cases. Limiting cases for $k = \infty$ and $k = 0$ transfer the given system into a new system (Table 9.9).

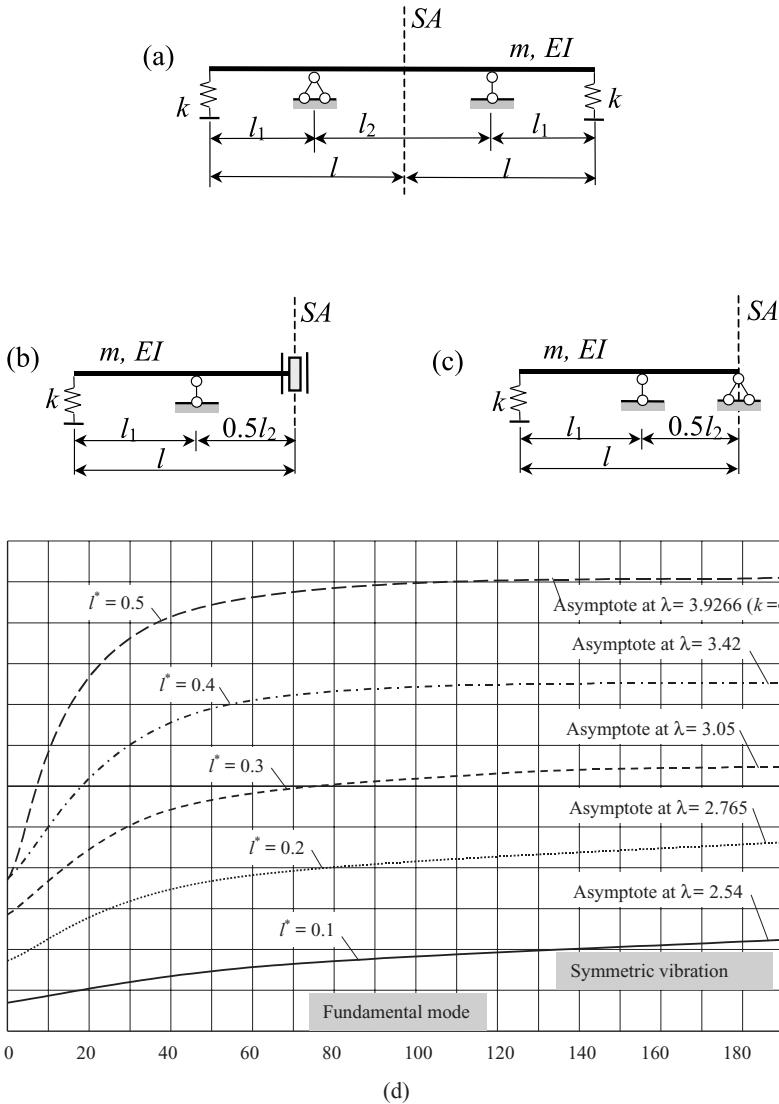

FIGURE 9.8. (a) Symmetrical three-span beam with elastic end supports; (b,c) Three-span uniform beam on elastic end supports; (d) Parameter λ as a function of $l^* = l_1/l$ and $k^* = kl^3/EI$ for the fundamental mode of vibration.

TABLE 9.9. Transformation of three-span beams: limiting cases of rigidity of elastic supports

	Symmetric vibration	Antisymmetric vibration
$k = \infty$	Pinned-pinned-guided Fig. 9.2(i)	Pinned-pinned-pinned Fig. 9.2(a)
$k = 0$	Free-pinned-guided Fig. 9.2(f)	Free-pinned-pinned Fig. 9.2(b)

9.3.3 Beam with clamped supports

A symmetric three-span continuous beam and its half-beam for symmetric and antisymmetric vibration are shown in Figs. 9.9(a), 9.9(b), and 9.9(c), respectively.

Analytical and numerical results for these cases are presented in Tables 9.3(c) and 9.5.

9.3.4 Beam with overhangs

A symmetric one-span beam with overhangs is presented in Fig. 9.10.

The analytical and numerical results for this case is presented in Chapter 4 and Tables 9.3(a) and 9.3(b).

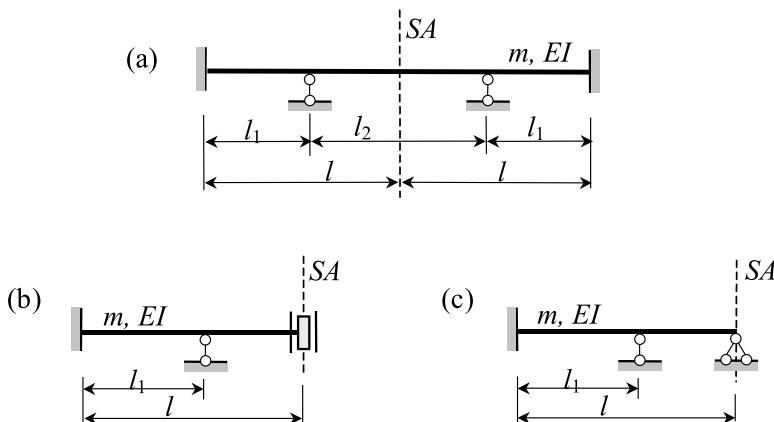

FIGURE 9.9. Symmetric system and half-system for symmetric and antisymmetric vibration.

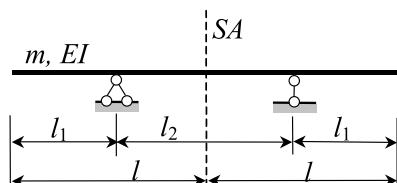

FIGURE 9.10. Design diagram.

Symmetrical vibration. In this case, the design diagram of half-beam is a free-pinned-guided beam (Table 9.3(b)).

Antisymmetric vibration. In this case, the design diagram of the half-beam is a free-pinned-pinned beam (Table 9.3(a)).

9.4 UNIFORM MULTISPAN BEAMS WITH EQUAL SPANS

The natural frequency of vibration of uniform multispan beams with equal spans is

$$\omega_i = \frac{\lambda_i^2}{l^2} \sqrt{\frac{EI}{m}}$$

The frequency parameters, λ , for uniform multispan beams with equal spans and different boundary conditions are presented in Table 9.10 (Bolotin, 1978).

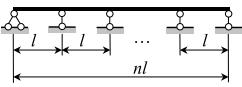

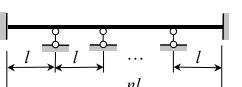

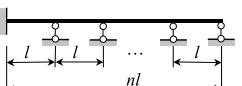

Eigenfunctions for prismatic multispan beams (number of spans, $n = 2, 3, 4$) with equal spans are shown in Appendix B (Korenev, 1970). These functions satisfy orthogonality conditions

$$\sum_{i=1}^{N-1} \int_0^1 X_{ri}(\xi) X_{ki}(\xi) d\xi = \begin{cases} 1 & r = k \\ 0 & r \neq k \end{cases} \quad (9.9)$$

where $\xi = x/l$; i is number of the spans, and k and r are numbers of the eigenfunctions.

The frequencies of vibrations of multispan beams with equal spans produce ‘ranges of extension’. In each of these zones the number of frequencies is equal to the number of spans, and the eigenvalues are closely spaced.

TABLE 9.10. Multispans uniform beams with equal spans: frequency parameters λ

Type of beam	Number of spans	Mode				
		1	2	3	4	5
	2	3.142	3.927	6.283	7.069	9.425
	3	3.142	3.550	4.304	6.283	6.692
	4	3.142	3.393	3.927	4.461	6.283
	5	3.142	3.299	3.707	4.147	4.555
	10	3.142	3.205	3.299	3.487	3.707
	2	3.927	4.744	7.069	7.855	10.210
	3	3.550	4.304	4.744	6.692	7.446
	4	3.393	3.927	4.461	4.744	6.535
	5	3.299	3.707	4.147	4.555	4.744
	10	3.205	3.299	3.487	3.707	3.927
	2	3.393	4.461	6.535	7.603	9.677
	3	3.267	3.927	4.587	6.409	7.069
	4	3.205	3.644	4.210	4.650	6.347
	5	3.205	3.487	3.927	4.367	4.681
	10	3.142	3.236	3.456	3.582	3.801

9.5 FREQUENCY EQUATIONS IN TERMS OF ZAL'TSBERG FUNCTIONS

The Zal'tsberg functions arise from equations (5.7) or (5.8) and may be presented in the form (Filippov, 1970)

$$\begin{aligned}\phi_i &= \coth \lambda_i - \cot \lambda_i; & \psi_i &= \csc \lambda_i - \operatorname{csch} \lambda_i; & \sigma_i &= 2 \frac{\cosh \lambda_i \cos \lambda_i - 1}{\sinh \lambda_i \sin \lambda_i} \\ \delta_i &= \frac{\cosh \lambda_i \cos \lambda_i + 1}{\sinh \lambda_i \sin \lambda_i}; & v_i &= \tanh \lambda_i + \tan \lambda_i\end{aligned}\quad (9.10)$$

where index i denotes the number of a span.

The natural frequency of vibration for a two-span beam with length of spans l_1 and l_2 is

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}} = \frac{\lambda_1^2}{l_1^2} \sqrt{\frac{EI}{m}}, \quad \lambda = \lambda_1 \frac{l_1 + l_2}{l_1}, \quad l = l_1 + l_2$$

If parameter λ_1 is a basic one (frequency parameters λ_i for all spans are presented in terms of frequency parameter λ_1 for first span), then the transfer to the basic parameter is $\lambda_2 = \lambda_1 \frac{l_2}{l_1}$.

9.5.1 Prismatic two-span beams with classic boundary conditions

Consider a pinned-pinned-pinned uniform beam with different lengths of the span (Fig. 9.11).

The frequency equation may be presented in the form

$$\phi_1 + \phi_2 = 0 \quad (9.11)$$

or, in explicit form, as

$$\coth \lambda_1 - \cot \lambda_1 + \coth \lambda_2 - \cot \lambda_2 = 0 \quad (9.11a)$$

where the frequency parameter for the i th span is

$$\lambda_i^2 = \omega l_i^2 \sqrt{\frac{m}{EI}}$$

Change from parameters λ_1 and λ_2 to parameter λ

$$\coth \alpha \lambda - \cot \alpha \lambda + \coth \eta \lambda - \cot \eta \lambda = 0 \quad (9.11b)$$

where $\alpha = \frac{l_1}{l}$, $\eta = 1 - \alpha$.

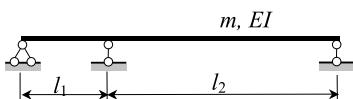

FIGURE 9.11. Design diagram.

If $EI_1 \neq EI_2$ then the frequency equation is

$$\frac{l_1}{EI_1}(\coth \lambda_1 - \cot \lambda_1) + \frac{l_2}{EI_2}(\coth \lambda_2 - \cot \lambda_2) = 0$$

Example. Find the eigenvalues of the two-span symmetric beam ($l_1 = l_2$) with a uniformly distributed mass.

Solution. The frequency equation is

$$\coth \lambda_1 - \cot \lambda_1 + \coth \lambda_2 - \cot \lambda_2 = 0 \quad \text{or} \quad \coth \lambda = \cot \lambda$$

The minimal root is $\lambda = 3.927$, which corresponds to symmetric vibration. As this takes place, the mode shape of each span coincides with the mode shape for the pinned-clamped beam. If, however, the beam vibrates according to the antisymmetric shape (in this case the eigenvalues of the system under investigation and the simple-supported beam are equal), then the bending moment at the middle support is zero. The frequency parameter values, λ , for the first modes of vibration as a function of the intermediate support spacing, l_1/l , are presented in Fig. 9.2(a).

Consider a pinned-pinned-clamped uniform beam with different lengths of the span (Fig. 9.12).

The frequency equation may be presented in the form (Filippov, 1970)

$$\frac{\phi(\lambda_1)}{\sigma(\lambda_2)} - \frac{1}{\phi(\lambda_2)} = 0 \quad (9.12)$$

or, in explicit form as

$$\frac{\sin \lambda_1 \cosh \lambda_1 - \sinh \lambda_1 \cos \lambda_1}{\sinh \lambda_1 \sin \lambda_1} + 2 \frac{1 - \cosh \lambda_2 \cos \lambda_2}{\sin \lambda_2 \cosh \lambda_2 - \sinh \lambda_2 \cos \lambda_2} = 0 \quad (9.12a)$$

The frequency of vibration equals

$$\omega = \frac{\lambda_1^2}{l_1^2} \sqrt{\frac{EI}{m}}$$

The first five frequency parameters, λ_i , as a function of ratio l_1/l_2 are presented in Table 9.11. The data presented in Table 9.11 also define the frequencies of the symmetric vibrations for a four-span beam that is symmetric with respect to the middle support.

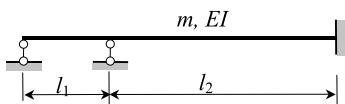

FIGURE 9.12. Design diagram.

9.5.2 Prismatic beams with special boundary conditions, $EI = \text{constant}$, $m = \text{constant}$

Two-span beams. Table 9.12 contains the design diagrams of uniform beams ($EI = \text{const. } m = \text{const.}$) with specific boundary conditions and corresponding frequency equations in terms of Zal'tsberg functions (Filippov, 1970).

In the limiting cases, the design diagrams are changed. For example, limiting case $l_2 = 0$ transfers diagrams 3 and 6 into the pinned-clamped beam with frequency equation

$$\tan \lambda_1 = \tanh \lambda_1 \quad (\text{see Table 5.3})$$

The limiting case $l_2 = 0$ or $l_1 = 0$ transfers diagrams 1 and 4 into the clamped-clamped beam with frequency equation

$$\cosh \lambda_1 \cos \lambda_1 = 1 \quad (\text{see Table 5.3}).$$

The equations presented in Table 9.12 may be used for calculation of three- and four-span symmetric beams.

TABLE 9.12. Uniform two-span beams with different spans and special boundary conditions: frequency equations in terms of Zal'tserg functions

Beam type	1	2	3
Frequency equation	$\frac{\sigma_1}{\phi_1} + \frac{\delta_2}{\phi_2} = 0$	$\frac{\sigma_1}{\phi_1} - \frac{\delta_2}{\phi_2} = 0$	$\phi_1 + v_2 = 0$
Beam type	4	5	6
Frequency equation	$\frac{\sigma_1}{\phi_1} - v_2 = 0$	$\phi_1 - \frac{\delta_2}{\phi_2} = 0$	$v_1 - \frac{\delta_2}{\phi_2} = 0$

Example. Derive the frequency equation of the symmetric vibration for the system shown in Fig. 9.13(a).

Solution. One-half of the system, which corresponds to symmetric vibration, is shown in Fig. 9.13(b).

In our case $\lambda_2 = 1.5\lambda_1$ (see Section 5.1.2).

The frequency equation is (Table 9.12, diagram 6)

$$v_1 - \frac{\delta_2}{\phi_2} = 0$$

In an explicit form, the frequency equation is given by

$$\tanh \lambda_1 + \tan \lambda_1 - \frac{\cosh \lambda_2 \cos \lambda_2 + 1}{\sinh \lambda_2 \sin \lambda_2 (\coth \lambda_1 - \cot \lambda_1)} = 0$$

The frequency equation in terms of λ_1 is

$$\tanh \lambda_1 + \tan \lambda_1 - \frac{\cosh 1.5\lambda_1 \cos 1.5\lambda_1 + 1}{\sinh 1.5\lambda_1 \sin 1.5\lambda_1 (\coth \lambda_1 - \cot \lambda_1)} = 0$$

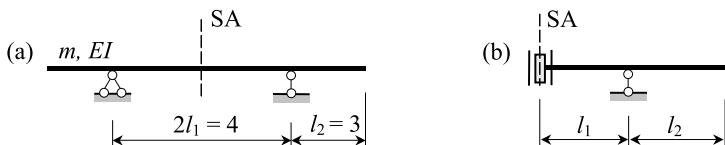

FIGURE 9.13. (a) Design diagram of the symmetrical system; (b) symmetrical vibration: one-half of the system; AS is axis of symmetry.

The natural frequency of vibration is

$$\omega = \frac{\lambda_1^2}{l_1^2} \sqrt{\frac{EI}{m}}$$

Multispan beam with n different spans. Figure 9.14 shows the multispan beam with n different spans.

The three-moments equations (5.7) for a continuous beam lead to the frequency equation

$$D = \begin{vmatrix} -(\phi_1 + \phi_2) & \psi_2 & 0 & \dots \\ \psi_2 & -(\phi_2 + \phi_3) & \psi_3 & \dots \\ 0 & \psi_3 & -(\phi_3 + \phi_4) & \dots \\ \dots & \dots & \dots & \dots \end{vmatrix} = 0 \quad (9.13)$$

where Hohenemser-Prager functions (see Table 5.2) are

$$\begin{aligned} \phi_k &= \coth \lambda_k - \cot \lambda_k \\ \psi_k &= \operatorname{cosech} \lambda_k - \operatorname{cosec} \lambda_k \end{aligned}$$

The frequency parameter for each element is

$$\lambda_k = \omega l_k^2 \sqrt{\frac{m_k}{EI_k}}$$

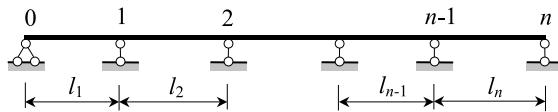

FIGURE 9.14. Multispan beam.

The index k points to the number of the span and its parameters.

The natural frequency of vibration is

$$\omega = \frac{\lambda_k^2}{l_k^2} \sqrt{\frac{EI_k}{m_k}}$$

9.6 BEAMS WITH LUMPED MASSES

9.6.1 Two-span uniform beams with equal spans and lumped masses

Figure 9.15(a) shows the symmetric two-span uniform beam with lumped masses.

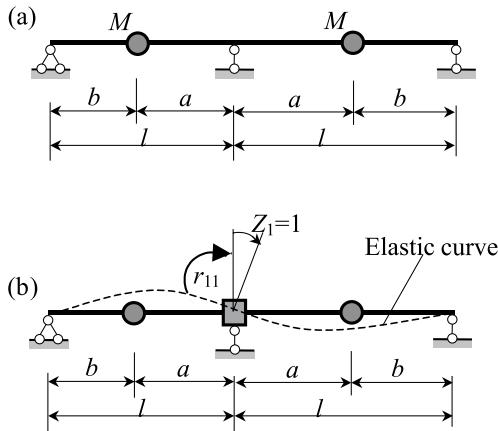

FIGURE 9.15. Design diagram and primary system of the slope-deflection method.

Antisymmetric vibration. The principal system of the slope and deflection method is presented in Fig. 9.15(b).

The principal unknown is the angle of rotation Z_1 . The canonical equation is $r_{11}Z_1 = 0$. The reaction r_{11} due to unit rotation of the support 1 equals (Table 4.8, case 5)

$$r_{11} = 2 \frac{kEI}{\Delta_1} \left\{ T^2 - V^2 + \frac{M\omega^2}{k^3 EI} [T_a TV_b + T_b TV_a - T_a T_b V - VV_a V_b] \right\} \quad (9.14)$$

where T and V are Krylov functions at $x = l$; T_a and V_a at $x = a$; T_b and V_b at $x = b$.

The frequency equation is

$$T^2 - V^2 + n\lambda[T_a TV_b + T_b TV_a - T_a T_b V - VV_a V_b] = 0 \quad (9.15)$$

or

$$2 \sinh \lambda \sin \lambda + n\lambda(\sin \lambda \sinh \xi_1 \lambda \sinh \xi_2 \lambda - \sinh \lambda \sin \xi_1 \lambda \sin \xi_2 \lambda) = 0 \quad (9.15a)$$

where $\frac{\omega^2 M}{k^3 EI} = n\lambda$, $n = \frac{M}{ml}$, $\xi_1 = \frac{a}{l}$, $\xi_2 = \frac{b}{l} = 1 - \xi_1$ (see section 5.2).

If $a = b = 0.5l$, then the frequency equation becomes

$$2 \sinh \lambda \sin \lambda + n\lambda \left(\sin \lambda \sinh^2 \frac{\lambda}{2} - \sinh \lambda \sin^2 \frac{\lambda}{2} \right) = 0, \quad \omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$$

The fundamental parameters, λ , as a function of mass ratio, n , are given in Table 9.13.

TABLE 9.13. Uniform symmetric two-span beam with two symmetrically located equal lumped masses: Fundamental frequency parameters λ

n	0.0	0.25	0.50	1.0	2.0	5.0	10.0	20.0	50.0	100	500	1000
λ	3.142	2.838	2.639	2.383	2.096	1.720	1.463	1.273	0.987	0.831	0.557	0.468

9.6.2 Uniform beams with equal spans and different lumped masses

Adjustment mass method. A multispan beam with arbitrary boundary conditions, equal spans and different lumped masses is shown in Fig. 9.16; the boundary conditions are not shown.

The natural frequency of vibration may be calculated by the formula

$$\omega_r = \frac{\lambda_r^2}{l^2} \sqrt{\frac{EI}{m_r}}$$

The frequency parameter, λ_r , for the r th mode of vibration of the beams with different boundary conditions and without lumped masses is given in Table 9.10.

The adjustment uniform mass, m_r , corresponding to the r -mode of vibration is

$$m_r = m + \frac{1}{l} \sum_{k=1}^n X_r(\xi_k) M_k, \quad \xi_k = \frac{x_k}{l} \quad (9.16)$$

Eigenfunctions $X_k(\xi_k)$, $\xi_k = \frac{x_k}{l}$, for multispan beams with different boundary conditions are presented in Appendix B (Korenev, 1970).

Example. Calculate the fundamental frequency of vibration for a pinned-pinned-clamped beam with two lumped masses M_1 and M_2 as shown in Fig. 9.17.

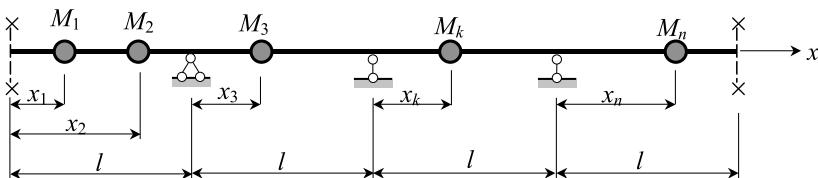

FIGURE 9.16. Multispan beam with different boundary conditions and lumped masses.

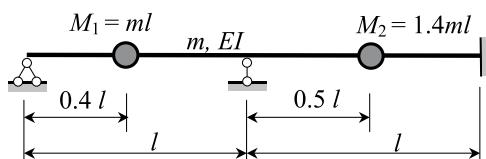

FIGURE 9.17. Multispan beam with distributed and lumped masses.

Solution. Parameter λ for a pinned-pinned-clamped beam equals 3.393 (Table 9.10). The ordinates of the first eigenfunction at point $x = 0.4l$ in the first span and at $x = 0.5l$ in the second span are 1.276 and 0.5435, respectively. So the uniform adjustment mass

$$m_1 = m + \frac{1}{l}(1.276^2 + 0.5435^2 \times 1.4)ml = m + 1.9236m = 2.9236m$$

The natural fundamental frequency of vibration is

$$\omega = \frac{3.393^2}{l^2} \sqrt{\frac{EI}{2.9236m}}$$

The adjustment mass method for one-span beams is presented in Chapter 7.

9.7 SLOPE AND DEFLECTION METHOD

This method is convenient to use for frequency analysis of beams and frames with different stiffness, length and mass density of elements.

Example. Derive the frequency equation for a three-span beam with different span length, stiffness and mass density. The system is presented in Fig. 9.18(a).

Solution. This beam contains two rigid joints, 1 and 2; consequently, the number of independent joint deflections is equal to two. In order to obtain the principal system of the slope and deflection method, the additional constraints introduced must prevent the rotation of all the rigid joints. The conjugate redundant system is presented in Fig. 9.18(b).

The canonical equations of the slope and deflection method are

$$\begin{aligned} r_{11}Z_1 + r_{12}Z_2 + R_{1p} &= 0 \\ r_{21}Z_1 + r_{22}Z_2 + R_{2p} &= 0 \end{aligned}$$

where R_{1p} and R_{2p} are the reactive moments developed by the additional constraints 1 and 2 under the action of loads P ; in the case of free vibration $R_{1p} = R_{2p} = 0$. The unit coefficients r_{11} and r_{21} are the reactive moments developed by the additional constraints 1 and 2 (first index) due to the rotation of the fixed joint 1 (second index) through an angle equal to unity. Unit coefficients r_{12} and r_{22} are the reactive moments developed by the additional constraints 1 and 2 due to the rotation of the fixed joint 2 through an angle equal to unity. The elastic curves due to the rotation of the fixed joints are shown as dashed lines, and the corresponding bending moment diagrams are shown as solid lines. The reactive moments at the ends of the each element may be calculated by using Smirnov functions (Chapter 4).

Consider Fig. 9.18(c), unit reactions are

$$r_{11} = \frac{4EI_1}{l_1} \psi_2(\lambda_1) + \frac{4EI_2}{l_2} \psi_2(\lambda_2); \quad r_{21} = \frac{2EI_2}{l_2} \psi_3(\lambda_2)$$

The indices of ψ (ψ_1 and ψ_2) denote the function number, i.e. a special type of function (Table 4.4), while the indices of λ (λ_1 and λ_2) denote the number of the span.

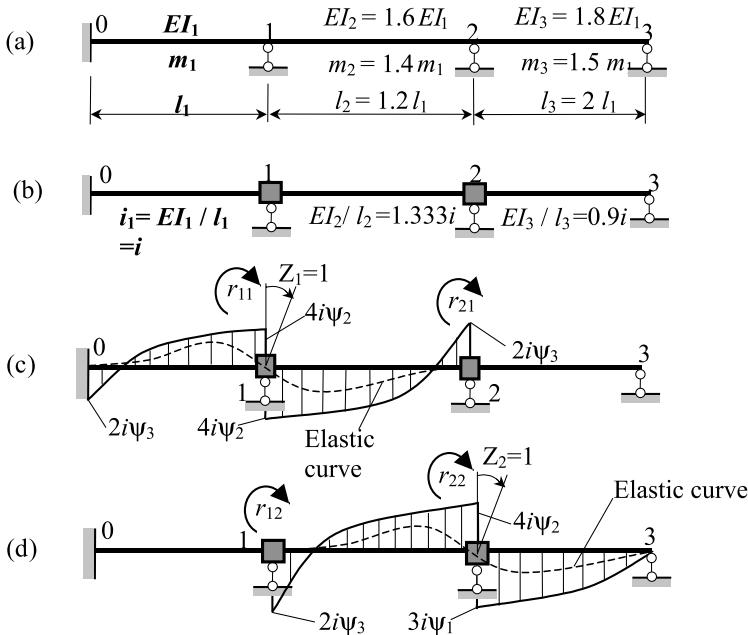

FIGURE 9.18. Continuous three-span clamped-pinned non-uniform beam. (a) Design diagram of multi-span beam; (b) conjugate redundant system; (c) bending moment diagram due to \$Z_1 = 1\$; (d) bending moment diagram due to \$Z_2 = 1\$.

Consider Fig. 9.18(d), unit reactions are

$$r_{22} = \frac{4EI_2}{l_2} \psi_2(\lambda_2) + \frac{3EI_3}{l_3} \psi_1(\lambda_3); \quad r_{12} = r_{21}$$

The frequency parameters are

$$\lambda_1 = l_1 \sqrt[4]{\frac{m_1 \omega^2}{EI_1}}; \quad \lambda_2 = l_2 \sqrt[4]{\frac{m_2 \omega^2}{EI_2}}; \quad \lambda_3 = l_3 \sqrt[4]{\frac{m_3 \omega^3}{EI_3}}$$

Let the base eigenvalue be \$\lambda_1 = l_1 \sqrt[4]{\frac{m_1 \omega^2}{EI_1}} = \lambda\$, then

$$\lambda_2 = \lambda \frac{l_2}{l_1} \sqrt[4]{\frac{m_2 EI_1}{m_1 EI_2}} = 1.0976\lambda; \quad \lambda_3 = \lambda \frac{l_3}{l_1} \sqrt[4]{\frac{m_3 EI_1}{m_1 EI_3}} = 1.91\lambda$$

The frequency equation is \$r_{11}r_{22} - r_{12}^2 = 0\$, where unit reactions in terms of the frequency parameter, \$\lambda\$, are

$$r_{11} = 4i\psi_2(\lambda) + 4 \times 1.333i\psi_2(1.0976\lambda)$$

$$r_{21} = 2 \times 1.333i\psi_3(1.0976\lambda); \quad r_{12} = r_{21}$$

$$r_{22} = 4 \times 1.333i\psi_2(1.0976\lambda) + 3 \times 0.9i\psi_1(1.91\lambda)$$

Smirnov's functions, ψ , which are required for calculation of the frequency of vibration are

$$\begin{aligned}\psi_1(\lambda) &= \frac{\lambda}{3} \frac{2 \sinh \lambda \sin \lambda}{\cosh \lambda \sin \lambda - \sinh \lambda \cos \lambda} \\ \psi_2(\lambda) &= \frac{\lambda}{4} \frac{\cosh \lambda \sin \lambda - \sinh \lambda \cos \lambda}{1 - \cosh \lambda \cos \lambda} \\ \psi_3(\lambda) &= \frac{\lambda}{2} \frac{\sinh \lambda - \sin \lambda}{1 - \cosh \lambda \cos \lambda}\end{aligned}$$

CHAPTER 10

PRISMATIC BEAMS UNDER COMPRESSIVE AND TENSILE AXIAL LOADS

This chapter focuses on prismatic Bernoulli–Euler beams under compressive and tensile loading. Analytic results for frequency equations and mode shape functions for beams with classical boundary conditions are presented. Galef's formula is discussed in detail. Upper and lower values for the frequency of vibrations are evaluated.

NOTATION

A	Cross-sectional area of the beam
E, ν	Modulus of elasticity and Poisson ratio of the beam material
EI	Bending stiffness
G	Gauge factor
i	Bending stiffness per unit length, $i = EI/l$
I	Moment of inertia of a cross-sectional area of the beam
k	Frequency parameter, $k^4 = \frac{m\omega^2}{EI}$
l	Length of the beam
M, N	Dimensionless frequency parameters
t	Time
T	Axial load
T_E	First Euler critical load
T_{mi}	Critical buckling load corresponding to mode i .
U, U_{mi}	Dimensionless parameter, $U = \frac{Tl^2}{2EI}, U_{mi} = \frac{T_{mi}l^2}{2EJ}$
x	Spatial coordinate
x, y, z	Cartesian coordinates
$X(x)$	Mode shape
$y(x, t), w$	Lateral displacement of the beam
ρ, m	Density of material and mass per unit length of beam, $m = \rho A$

λ	Frequency parameter, $\lambda^2 = k^2 l^2$
ω	Circular natural frequency of the transverse vibration of a compressed beam (relative natural frequency)
ω_{0i}	Circular natural frequency of transverse vibration of a beam with no axial force in the i th mode of vibration
Ω	Dimensionless natural frequency parameter of a compressed beam (relative natural frequency); $\Omega = \omega l^2 / \alpha$, $\alpha^2 = EI / \rho A$
$\Omega^* = \Omega / \Omega_{0i}$	Normalized natural frequency parameter
Ω_{0i}	Dimensionless natural frequency parameter of a beam with no axial force in the i th mode of vibration; $\Omega_{0i} = \omega_{0i} l^2 / \alpha$,

10.1 BEAMS UNDER COMPRESSIVE LOAD

10.1.1 Principal equations

The notation for a beam without axial load and under compressive constant axial load T is presented in Figs. 10.1(a) and (b), respectively; boundary conditions of the beam are not shown. Parameter $\alpha^2 = EI / \rho A$.

Notation

- ω_{0i} and $\Omega_{0i} = \omega_{0i} l^2 / \alpha$ are the circular natural frequency and dimensionless natural frequency parameters of the beam with no axial force in the i th mode of vibration;
- ω and $\Omega = \omega l^2 / \alpha$ are the circular natural frequency and dimensionless natural frequency parameters of the compressed beam (relative natural frequency);
- $\Omega^* = \Omega / \Omega_{0i}$ is the normalized natural frequency parameter.

Differential equation of vibration

$$EI \frac{\partial^4 y}{\partial x^4} + T \frac{\partial^2 y}{\partial x^2} + \rho A \frac{\partial^2 y}{\partial t^2} = 0 \quad (10.1)$$

Solution

$$y(x, t) = X(x) \cos \omega t$$

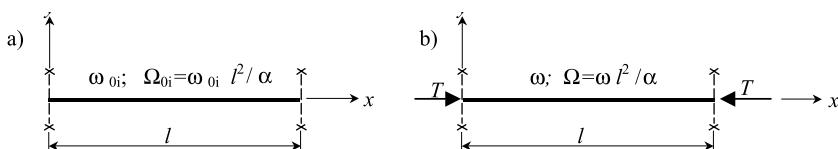

FIGURE 10.1. Notation of a beam (a) Beam without axial load; (b) Beam under axial compressed load.

Differential equation for modal displacement

$$EI \frac{d^4 X}{dx^4} + T \frac{d^2 X}{dx^2} - \rho A \omega^2 X = 0 \quad (10.2)$$

Modal displacement. Form 1

$$X(x) = X(l\xi) = C_1 \sinh M\xi + C_2 \cosh M\xi + C_3 \sin N\xi + C_4 \cos N\xi \quad (10.3)$$

where $\xi = x/l$ is a dimensionless beam coordinate;

$C_i (i = 1, 2, 3, 4)$ are constants to be determined from the boundary conditions; M and N are parameters, which may be written as

$$\begin{aligned} M &= l \cdot \sqrt{-\left(\frac{T}{2EI}\right) + \sqrt{\left(\frac{T}{2EI}\right)^2 + \left(\frac{\rho A}{EI}\right)\omega^2}} = \sqrt{-U + \sqrt{U^2 + \Omega^2}} \\ N &= l \cdot \sqrt{\left(\frac{T}{2EI}\right) + \sqrt{\left(\frac{T}{2EI}\right)^2 + \left(\frac{\rho A}{EI}\right)\omega^2}} = \sqrt{U + \sqrt{U^2 + \Omega^2}} \end{aligned} \quad (10.3a)$$

$U = Tl^2/2EI$ is a dimensionless compression parameter (the relative axial force); $\Omega = \omega l^2/\alpha$, $\alpha^2 = EI/m$ is a dimensionless natural frequency of vibration.

Form 2 (Initial parameter form) (Nowacki, 1963)

$$X(\xi) = X(0)[H(\xi) + \alpha^2 F(\xi)] + X'(0)[G(\xi) + \alpha^2 E(\xi)] + X''(0)F(\xi) + X'''(0)E(\xi) \quad (10.4)$$

where $X(0)$, $X'(0)$, $X''(0)$ and $X'''(0)$ are lateral displacement, slope, bending moment, and shear force at $x = 0$

$$\begin{aligned} E(\xi) &= \frac{1}{N^2 + M^2} \left(\frac{1}{M} \sinh M\xi - \frac{1}{N} \sin N\xi \right) \\ F(\xi) &= \frac{1}{N^2 + M^2} (\cosh M\xi - \cos N\xi) \\ G(\xi) &= \frac{1}{N^2 + M^2} (M \sinh M\xi + N \sin N\xi) \\ H(\xi) &= \frac{1}{N^2 + M^2} (M^2 \cosh M\xi + N^2 \cos N\xi) \end{aligned} \quad (10.4a)$$

Galef's formula is a useful relationship between the frequency of vibration and the critical load of the compressed beam. The existence of this relationship is obviously because the frequency of vibration and the critical load are eigenvalues of the deformable system.

For bending vibration, it is worthwhile to cite Amba-Rao (1967) and Bokaian (1988) for Galef's formula:

The fundamental natural frequency of a compressed beam/natural frequency of uncompressed beam = $(1 - \text{compressive load/Euler buckling load})^{0.5}$.

$$\begin{aligned} \Omega^* &= \sqrt{1 - U^*} \\ \Omega^* &= \frac{\Omega}{\Omega_{0i}} = \frac{\omega}{\omega_{0i}}, \quad i = 1 \quad \text{and} \quad U^* = \frac{T}{T_E} \end{aligned} \quad (10.5)$$

where T_E is the Euler critical buckling load in the first mode and U^* is the normalized compression force parameter.

1. Galef's formula for the fundamental mode of vibration is
 - (a) exact for pinned-pinned, sliding-pinned and sliding-sliding beams;
 - (b) approximate for sliding-free, clamped-free, clamped-pinned, clamped-clamped and clamped-sliding beams;
 - (c) not valid for pinned-free and free-free beams.
2. Galef's formula is valid for the third and higher modes of vibrations for all types of boundary conditions.

Example. Find the fundamental frequency of vibration of the pinned-pinned uniform beam under compressive load, if $T/T_{cr} = 0.2$ (Fig. 10.2).

Solution. According to Galef's formula

$$\Omega^* = \sqrt{1 - U^*} \quad \Omega^* = \frac{\Omega}{\Omega_{0i}} = \frac{\omega}{\omega_{0i}}, \quad i = 1, \quad U^* = \frac{T}{T_e}$$

so the fundamental frequency of vibration of a compressed beam equals

$$\omega = \omega_0 \sqrt{1 - \frac{T}{T_e}} = \frac{3.14159^2}{l^2} \sqrt{\frac{EI}{m}} \sqrt{1 - 0.2} = \frac{2.97113^2}{l^2} \sqrt{\frac{EI}{m}}$$

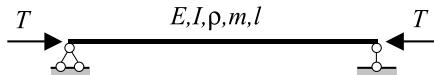

FIGURE 10.2. Pinned-pinned uniform beam under compressive axial load.

10.1.2 Frequency equations

Table 10.1. contains the frequency equation for compressed beams with classical boundary conditions (Bokaian, 1988). Parameters M and N are presented in Section 10.1.1. The relative natural frequency parameter and the frequency of vibration are

$$\Omega = \frac{\omega l^2}{a} = \lambda_i^2 \quad \omega_i = \frac{\lambda_i^2}{l^2} \sqrt{\frac{EI}{\rho A}}$$

Table 10.2 predicts eigenvalues for axial compressed beams. They include the critical load and frequency of vibration for beams with different boundary conditions.

The critical buckling load parameter corresponding to the i th mode is $U_{mi} = T_{mi} l^2 / 2EI$.

10.1.3 Modal displacement and mode shape coefficients

The modal displacement may be written in the form

$$X(x) = X(l\xi) = C_1 \sinh M\xi + C_2 \cosh M\xi + C_3 \sin N\xi + C_4 \cos N\xi \quad (10.6)$$

The mode shape coefficients C_n ($n=1, 2, 3, 4$) for a beam with different boundary conditions are presented in Table 10.3 (Bokaian, 1988). Parameters M and N are listed in Section 10.1.1, formulae (10.3a).

TABLE 10.1. Uniform one-span beams with different boundary conditions under compressive axial load: frequency equations

Beam type	Boundary condition		Frequency equation
	Left end ($x = 0$)	Right end ($x = l$)	
Free-free 	$X''(0) = 0$ $X'''(0) + (T/EI)X'(0) = 0$	$X''(l) = 0$ $X'''(l) + (T/EI)X'(l) = 0$	$\Omega^3[1 - \cosh M \cos N] + (4U^3 + 3U\Omega^2) \sinh M \sin N = 0$
Sliding-free 	$X'(0) = 0$ $X'''(0) = 0$	$X''(l) = 0$ $X'''(l) + (T/EI)X'(l) = 0$	$M^3 \cosh M \sin N + N^3 \cos N \sinh M = 0$ or $M^3 \tan N + N^3 \tanh M = 0$
Clamped-free 	$X(0) = 0$ $X'(0) = 0$	$X''(l) = 0$ $X'''(l) + (T/EI)X'(l) = 0$	$\Omega^2 - \Omega U \sinh M \sin N + (2U^2 + \Omega^2) \cosh M \cos N = 0$
Pinned-free 	$X(0) = 0$ $X''(0) = 0$	$X''(l) = 0$ $X'''(l) + (T/EI)X'(l) = 0$	$N^3 \cosh M \sin N - M^3 \sinh M \cos N = 0$ or $N^3 \tan N - M^3 \tanh M = 0$
Pinned-pinned 	$X(0) = 0$ $X''(0) = 0$	$X(l) = 0$ $X''(l) = 0$	$\sin N = 0$
Clamped-pinned 	$X(0) = 0$ $X'(0) = 0$	$X(l) = 0$ $X''(l) = 0$	$M \cosh M \sin N - N \sinh M \cos N = 0$ or $M \tan N - N \tanh M = 0$
Clamped-clamped 	$X(0) = 0$ $X'(0) = 0$	$X(l) = 0$ $X'(l) = 0$	$\Omega - U \sinh M \sin N - \Omega \cosh M \cos N = 0$
Clamped-sliding 	$X(0) = 0$ $X'(0) = 0$	$X'(l) = 0$ $X'''(l) = 0$	$N \cosh M \sin N + M \sinh M \cos N = 0$ or $N \tan N + M \tanh M = 0$
Sliding-pinned 	$X'(0) = 0$ $X'''(0) = 0$	$X(l) = 0$ $X''(l) = 0$	$\cos N = 0$
Sliding-sliding 	$X'(0) = 0$ $X'''(0) = 0$	$X'(l) = 0$ $X'''(l) = 0$	$\sin N = 0$

Special case: If compressed load $T = 0$, then $U = V = 0$ and $M = N = \lambda$.

Example. Find the frequencies of vibration for the simply-supported compressed beam shown in Fig. 10.2.

Solution. The frequency equation is $\sin N = 0$, so $N = i\pi$, $i = 1, 2, \dots$

$$\sqrt{U + \sqrt{U^2 + \Omega^2}} = i\pi$$

TABLE 10.2. Uniform one-span beams with different boundary conditions under compressive axial load: frequency parameter and critical buckling load

Beam type	Critical buckling load parameter U_{mi}	Euler critical buckling load T_E	Parameter Ω_{0i}	Galef formula for first mode
Free-free	$i^2\pi^2/2$	π^2EI/l^2	$(2i+1)^2\pi^2/4^\dagger$	Not valid
				
Sliding-free	$(2i-1)^2\pi^2/8$	$\pi^2EI/4l^2$	$(4i-1)^2\pi^2/16^\dagger$	Approximate
				
Clamped-free	$(2i-1)^2\pi^2/8$	$\pi^2EI/4l^2$	$(2i-1)^2\pi^2/4$	Approximate
				
Pinned-free	$i^2\pi^2/2$	π^2EI/l^2	$(4i+1)^2\pi^2/16^\dagger$	Not valid
				
Pinned-pinned	$i^2\pi^2/2$	π^2EI/l^2	$i^2\pi^2$	$\Omega^* = \sqrt{1 - U^*}$

Sliding-pinned	$(2i-1)^2\pi^2/8$	$\pi^2EI/4l^2$	$(2i-1)^2\pi^2/4$	$\Omega^* = \sqrt{1 - U^*}$
				
Sliding-sliding	$i^2\pi^2/2$	π^2EI/l^2	$i^2\pi^{2\dagger}$	$\Omega^* = \sqrt{1 - U^*}$
				

[†] The asymptotic formulas are also presented in Table 5.1. The numerical results concerning variation of Ω with U for beams with classical boundary conditions are presented by Bokaian (1988).

Because $U = \frac{Tl^2}{2EI}$ and $\Omega = \omega l^2 \sqrt{\frac{m}{EI}}$, the expression for N leads to the exact expression for the frequency of the system

$$\omega_i = \frac{i^2\pi^2}{l^2} \sqrt{\frac{EI}{m}} \sqrt{1 - \frac{T}{EIi^2\pi^2}} \frac{l^2}{p^2}$$

Sliding-pinned 	0	0	0	1
Sliding-sliding 	0	0	0	1

Let $i = 1$ (fundamental mode) and $T/T_E = 0.3$. In this case, the frequency of vibration is

$$\omega = \omega_0 \sqrt{1 - 0.3} = 0.8366\omega_0, \quad \omega_0 = \frac{\pi^2}{l^2} \sqrt{\frac{EI}{m}}$$

Calculate the following parameters

$$U = \frac{Tl^2}{2EI} = \frac{0.3T_E l^2}{2EI} = \frac{0.3 \times \pi^2 EI}{l^2} \frac{l^2}{2EI} = 1.4804$$

$$\Omega = \omega l^2 \sqrt{\frac{m}{EI}} = 0.8336\omega_0 l^2 \sqrt{\frac{m}{EI}} = 8.2569$$

$$\sqrt{U + \sqrt{U^2 + \Omega^2}} = \sqrt{1.4804 + \sqrt{1.4804^2 + 8.2569^2}} = 3.1415$$

The modal displacement is

$$X(x) = \sin \left[(U + \sqrt{U^2 + \Omega^2})^{1/2} \frac{x}{l} \right] = \sin 3.1415 \frac{x}{l}$$

Example. Find the frequencies of vibration for a clamped–pinned compressed beam, if $T/T_E = 0.3$.

Solution. The frequency equation is

$$M \cosh M \sin N - N \sinh M \cos N = 0$$

The first Euler critical force, $T_E = \frac{\pi^2 EI}{(0.7l)^2}$, so parameter

$$U = \frac{Tl^2}{2EI} = 0.3T_E \frac{l^2}{2EI} = 3.0201$$

and the frequency equation becomes

$$\frac{\sqrt{-3.0201 + \sqrt{3.0201^2 + \Omega^2}}}{\sqrt{3.0201 + \sqrt{3.0201^2 + \Omega^2}}} \tan \left(\sqrt{3.0201 + \sqrt{3.0201^2 + \Omega^2}} \right) - \tanh \left(\sqrt{-3.0201 + \sqrt{3.0201^2 + \Omega^2}} \right) = 0$$

The root of this equation is $\Omega = \omega l^2 \sqrt{\frac{m}{EI}} = 12.954$, so the fundamental frequency of vibration of a compressed clamped–pinned beam equals

$$\omega = \frac{12.954}{l^2} \sqrt{\frac{EI}{m}} = \frac{3.599^2}{l^2} \sqrt{\frac{EI}{m}}$$

If $T = 0$, then $\omega = \frac{3.9266^2}{l^2} \sqrt{\frac{EI}{m}}$.

Parameters

$$M = \sqrt{-3.0201 + \sqrt{3.0201^2 + \Omega^2}} = 3.2064$$

$$N = \sqrt{3.0201 + \sqrt{3.0201^2 + \Omega^2}} = 4.0399$$

The mode shape coefficients are

$$C_1 = 1, \quad C_2 = -\tanh M = -0.9967$$

$$C_3 = -\frac{M}{N} = -0.7937, \quad C_4 = \frac{M}{N} \tan N = 0.9968$$

The modal displacement and slope are

$$\begin{aligned} X(x) &= X(l\xi) = \sinh 3.2064\xi - 0.9967 \cosh 3.2064\xi - 0.7937 \sin 4.0399\xi \\ &\quad + 0.9968 \cos 4.0399\xi \\ X'(l\xi) &= 3.2064 \cosh 3.2064\xi - 3.1958 \sinh 3.2064\xi - 3.2065 \cos 4.0399\xi \\ &\quad - 4.0273 \sin 4.0399\xi \end{aligned}$$

10.2 SIMPLY SUPPORTED BEAM WITH CONSTRAINTS AT AN INTERMEDIATE POINT

The design diagram of the compressed simply supported uniform beam with translational and rotational spring supports at an intermediate point, is presented in Fig. 10.3.

The differential equation for eigenfunctions in the i th mode is

$$X_i^{IV} + k^2 X_i'' - \lambda^4 X_i = 0, \quad i = 1, 2 \quad (10.7)$$

where

$$k^2 = \frac{Tl^2}{EI} = 2U, \quad \omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$$

Boundary and compatibility conditions are

$$\begin{array}{ll} x = 0 & X_1 = X_1'' = 0 \\ x = l - c & X_1 = X_2; \quad X'_1 = X'_2, \quad k_1^* X'_1 + X''_1 = X''_2, \quad X'''_1 - k_2^* X_1 = X''_2 \\ x = l & X_2 = X''_2 = 0 \end{array} \quad (10.8)$$

where the dimensionless parameters of rotational and translational spring supports are, respectively

$$k_1^* = \frac{k_{\text{rot}}l}{EI}, \quad k_2^* = \frac{k_{\text{tr}}l^3}{EI}$$

The fundamental natural frequencies parameter λ for a simply-supported beam with axial compressive force and various restraint parameters and their spacing are presented in Table 10.4 (Liu and Chen, 1989). The normalized compression force parameter and the

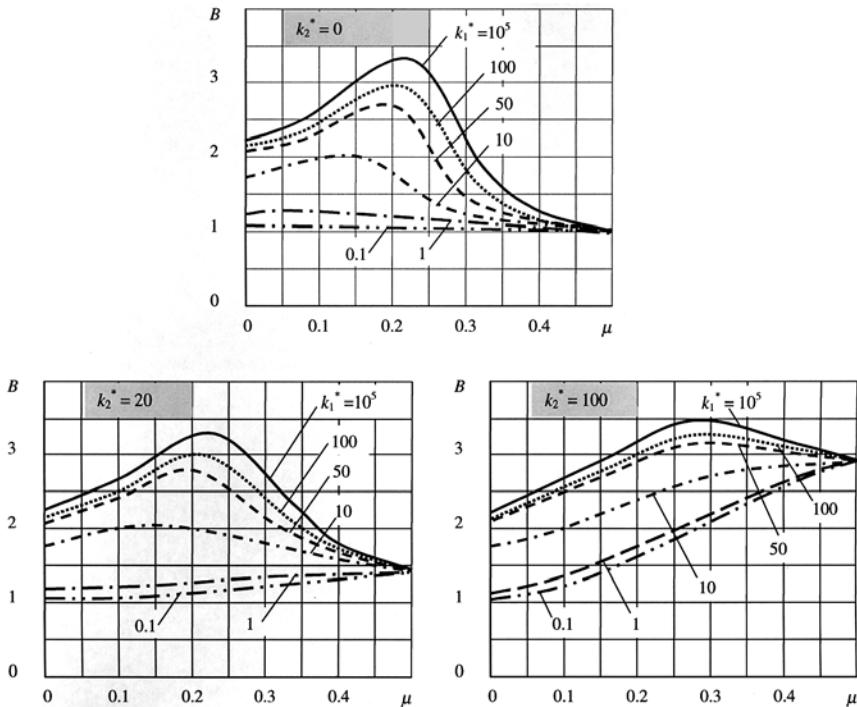

FIGURE 10.4. Buckling coefficient B for a simply-supported compressed beam with elastic restrictions at any point for various parameters $k_1^* = k_{\text{rot}}l/EI$, $k_2^* = k_{\text{tr}}l^3/EI$ and spacing ratio $\mu = c/l$.

Euler critical buckling load in the first mode for a pinned-pinned beam without elastic constraints are

$$\alpha = \frac{T}{T_{\text{cr}}}, \quad T_{\text{cr}} = \frac{\pi^2 BEI}{l^2}$$

The buckling coefficients B for a pinned-pinned beam with various values of k_1^* , k_2^* , and spacing ratio c/l are presented in Fig. 10.4.

10.3 BEAMS ON ELASTIC SUPPORTS AT THE ENDS

A uniform one-span beam with ends elastically restrained against translation and rotation and initially loaded with an axial constant compressive force T is presented in Fig. 10.5.

Differential equation of vibration

$$EI \frac{\partial^4 y}{\partial x^4} + T \frac{\partial^2 y}{\partial x^2} + \rho A \frac{\partial^2 y}{\partial t^2} = 0 \quad (10.9)$$

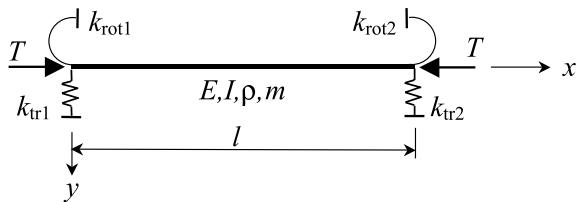

FIGURE 10.5. Compressed beam with elastic restrictions at both ends.

Boundary Conditions

$$\begin{aligned} \text{at } x = 0: \quad K_{\text{rot}1} \frac{\partial y(0, t)}{\partial x} &= EI \frac{\partial^2 y(0, t)}{\partial x^2} & EI \frac{\partial^3 y(0, t)}{\partial x^3} &= -K_{\text{tr}1} y(0, t) - T \frac{\partial y(0, t)}{\partial x} \\ \text{at } x = l: \quad K_{\text{rot}2} \frac{\partial y(l, t)}{\partial x} &= -EI \frac{\partial^2 y(l, t)}{\partial x^2} & EI \frac{\partial^3 y(l, t)}{\partial x^3} &= -K_{\text{tr}2} y(l, t) - T \frac{\partial y(l, t)}{\partial x} \end{aligned} \quad (10.10)$$

Solution

$$y(x, t) = X(x) \cos \omega t$$

The differential equation for modal displacement is

$$EI \frac{d^4 X}{dx^4} + T \frac{d^2 X}{dx^2} - \rho A \omega^2 X = 0$$

Modal displacement

$$X(x) = X(l\xi) = C_1 \sinh M\xi + C_2 \cosh M\xi + C_3 \sin N\xi + C_4 \cos N\xi$$

$$M = l \sqrt{-\left(\frac{T}{2EI}\right) + \sqrt{\left(\frac{T}{2EI}\right)^2 + \left(\frac{\rho A}{EI}\right)\omega^2}} = \sqrt{-U + \sqrt{U^2 + \Omega^2}} \quad (10.11)$$

$$N = l \sqrt{\left(\frac{T}{2EI}\right) + \sqrt{\left(\frac{T}{2EI}\right)^2 + \left(\frac{\rho A}{EI}\right)\omega^2}} = \sqrt{U + \sqrt{U^2 + \Omega^2}}$$

where $U = Tl^2/2EI$ is the dimensionless compression parameter and $\Omega = \omega l^2/\alpha$ is the dimensionless natural frequency parameter of the compressed beam, $\alpha^2 = EI/\rho A$.

The frequency equation may be written as follows (Maurizi and Belles, 1991)

$$\begin{aligned}
 & T_1 T_2 R_1 R_2 \{(\cos N \cosh M - 1)[2M^5 N^5 + 4U(M^3 N^5 - M^5 N^3) - 8U^2 M^3 N^3] \\
 & + \sin N \sinh M[(M^4 N^6 - M^6 N^4) - 8UM^4 N^4 + 4U^2(M^4 N^2 - M^2 N^4)]\} \\
 & + (R_1 T_1 T_2 + R_2 T_1 T_2) \{(\sin N \cosh M[(M^5 N^4 + M^3 N^6) - 2U(M^5 N^2 + M^3 N^4)] \\
 & + \cos N \sinh M[(M^4 N^5 + M^6 N^3) + 2U(M^2 N^5 + M^4 N^3)]\} \\
 & + T_1 T_2 \sin N \sinh M(M^6 N^2 + M^2 N^6 + 2M^4 N^4) \\
 & + (R_1 R_2 T_1 + R_1 R_2 T_2) (\sin N \cosh M[(M^5 N^2 + M^3 N^4) + 2U(M^3 N^2 + MN^4)] \\
 & - \cos N \sinh M[(M^2 N^5 + M^4 N^3) + 2U(M^2 N^3 + M^4 N)]) \\
 & - (R_1 T_2 + R_2 T_1) \cos N \cosh M[(M^5 N + MN^5) + 8M^3 N^3] \\
 & - (R_1 T_1 + R_2 T_2) [(MN^5 + M^5 N) + 2M^3 N^3 \cos N \cosh M \\
 & + 2U(MN^3 - M^3 N)(\cos N \cosh M - 1) \\
 & - (M^4 N^2 - M^2 N^4 + 4U^2 M^2 N) \sin N \sinh M] \\
 & - (T_1 + T_2) [(M^3 N^2 + MN^4) \sin N \cosh M + (M^2 N^3 + M^4 N) \cos N \sinh M] \\
 & - R_1 R_2 (M^4 + N^4 + 2M^2 N^2) \sin N \sinh M - (M^2 - N^2) \sin N \sinh M \\
 & - (R_1 + R_2) [(M^3 + MN^2) \sin N \cosh M - (N^3 + M^2 N) \cos N \sinh M] \\
 & + 2M^3 N^3 (\cos N \cosh M - 1) = 0
 \end{aligned}$$

where the dimensionless stiffness parameters are

$$R_1 = \frac{EI}{K_{r1}l}, \quad T_1 = \frac{EI}{K_{t1}l^3}, \quad R_2 = \frac{EI}{K_{r2}l}, \quad T_2 = \frac{EI}{K_{t2}l^3}$$

To reduce the system presented in Fig. 10.5 to the system with classical boundary conditions, the stiffness coefficients in the above frequency equation must be changed accordingly, data presented in Table 10.5.

10.4 BEAMS UNDER TENSILE AXIAL LOAD

10.4.1 Principal equations

The notation for a beam without axial load and under tensile constant axial load T is presented in Figs. 10.6(a) and (b), respectively; the boundary conditions of the beams are not shown.

Parameter $\alpha^2 = EI/\rho A$.

Notation

- ω_{0i} and $\Omega_{0i} = \omega_{0i} l^2 / \alpha$ are the circular natural frequency and the dimensionless natural frequency parameters of a beam with no axial force in the i th mode of vibration;
- ω and $\Omega = \omega l^2 / \alpha$ are the circular natural frequency and the dimensionless natural frequency parameter of a compressed beam (relative natural frequency);
- $\Omega^* = \Omega / \Omega_{0i}$ is the normalized natural frequency parameter.

The differential equation of vibration

$$EI \frac{d^4 y}{dx^4} - T \frac{d^2 y}{dx^2} + \rho A \frac{d^2 y}{dt^2} = 0 \quad (10.12)$$

Solution

$$y(x, t) = X(x) \cos \omega t$$

The differential equation for modal displacement is

$$EI \frac{d^4 X}{dx^4} - T \frac{d^2 X}{dx^2} - \rho A \omega^2 X(x) = 0 \quad (10.13)$$

Modal displacement

$$X(x) = X(l\xi) = C_1 \sinh M\xi + C_2 \cosh M\xi + C_3 \sin N\xi + C_4 \cos N\xi, \quad \xi = \frac{x}{l} \quad (10.14)$$

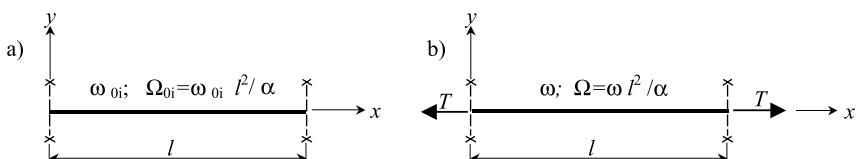

FIGURE 10.6. Notation of a beam. (a) Beam without axial load; (b) Beam under axial tensile load.

As opposed to compressed beams (Section 10.1.1) the parameters M and N are

$$\begin{aligned} M &= l \sqrt{\left(\frac{T}{2EI}\right) + \sqrt{\left(\frac{T}{2EI}\right)^2 + \left(\frac{\rho A}{EI}\right)\omega^2}} = \sqrt{U + \sqrt{U^2 + \Omega^2}} \\ N &= l \sqrt{\left(\frac{T}{2EI}\right) + \sqrt{\left(\frac{T}{2EI}\right)^2 + \left(\frac{\rho A}{EI}\right)\omega^2}} = \sqrt{-U + \sqrt{U^2 + \Omega^2}} \end{aligned} \quad (10.14a)$$

The modal shape coefficients C_k , $k = 1, 2, 3, 4$ are presented in Table 10.7.

10.4.2 Relationship of the normalized natural frequency parameter, Ω^* , with the normalized tension parameter, U^*

The Rayleigh quotient is

$$\omega^2 = \frac{\int_0^l EIX''^2 dx}{\int_0^l mX^2 dx} \left[1 + \frac{\beta_1}{\beta_2} \right] \quad (10.15)$$

where parameters β_1 and β_2 are

$$\beta_1 = T \int_0^l X'^2 dx \quad \beta_2 = \int_0^l EIX''^2 dx$$

so the normalized natural frequency parameter Ω^* may be presented in the form

$$\Omega^* = \sqrt{1 + \gamma U^*} \quad (10.16)$$

This relationship ($\Omega^* - U^*$) is exact if the exact $X(x)$ is employed, and is only true if the vibrating mode shape is identical with the buckling mode shape. So, for pinned-pinned, sliding-pinned and sliding-sliding beams, the coefficient $\gamma = 1$. The values of coefficient γ for a beam with different boundary conditions are presented in Table 10.9.

For third and higher modes of vibration, the expression $\Omega^* = \sqrt{1 + U^*}$ is valid for any boundary conditions of one-span beams. The exact frequency equations for a beam with different boundary conditions are presented in Table 10.6.

Frequency equations. The dimensionless parameters M and N for tensile beams are (Bokaian, 1990)

$$M = (U + \sqrt{U^2 + \Omega^2})^{1/2}, \quad N = (-U + \sqrt{U^2 + \Omega^2})^{1/2}$$

The Table 10.6 contains the frequency equation for uniform one-span beams with different boundary conditions under tensile axial load.

Example. Find the fundamental frequency of vibration of the pinned-pinned uniform beam under tensile axial load (Fig. 10.7)

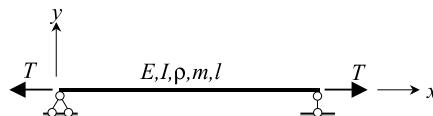

FIGURE 10.7. Pinned-pinned uniform beam under tensile axial load.

TABLE 10.6. Uniform one-span beams with different boundary conditions under tensile axial load: frequency equation

Beam type	Boundary condition		Frequency equation	
	Left end ($x = 0$)	Right end ($x = l$)		
Free-free			$\Omega^3[1 - \cosh M \cos N]$ $-(4U^3 + 3U\Omega^2) \sinh M \sin N = 0$

Sliding-free		$X'(0) = 0$ $X''(0) = 0$	$X''(l) = 0$ $X''' - (T/EI)X' = 0$	$M^3 \cosh M \sin N + N^3 \cos N \sinh M = 0$ or $(M^3 \tan N + N^3 \tanh M = 0)$
Clamped-free		$X(0) = 0$ $X'(0) = 0$	$X''(l) = 0$ $X'''(l) - (T/EI)X'(l) = 0$	$\Omega^2 + \Omega U \sinh M \sin N$ $+(2U^2 + \Omega^2) \cosh M \cos N = 0$
Pinned-free		$X(0) = 0$ $X''(0) = 0$	$X''(l) = 0$ $X'''(l) - (T/EI)X'(l) = 0$	$N^3 \cosh M \sin N - M^3 \sinh M \cos N = 0$ or $(N^3 \tan N - M^3 \tanh M = 0)$
Pinned-pinned		$X(0) = 0$ $X''(0) = 0$	$X(l) = 0$ $X''(l) = 0$	$\sin N = 0$
Clamped-pinned		$X(0) = 0$ $X'(0) = 0$	$X(l) = 0$ $X''(l) = 0$	$M \cosh M \sin N - N \sinh M \cos N = 0$ or $(M \tan N - N \tanh M = 0)$
Clamped-clamped		$X(0) = 0$ $X'(0) = 0$	$X(l) = 0$ $X'(l) = 0$	$\Omega + U \sinh M \sin N - \Omega \cosh M \cos N = 0$
Clamped-sliding		$X(0) = 0$ $X'(0) = 0$	$X'(l) = 0$ $X'''(l) = 0$	$N \cosh M \sin N + M \sinh M \cos N = 0$ or $(N \tan N + M \tanh M = 0)$
Sliding-pinned		$X'(0) = 0$ $X''(0) = 0$	$X(l) = 0$ $X''(l) = 0$	$\cos N = 0$
Sliding-sliding		$X'(0) = 0$ $X'''(0) = 0$	$X'(l) = 0$ $X'''(l) = 0$	$\sin N = 0$

Solution. The frequency equation for a pinned-pinned beam is $\sin N = 0$, so $N = i\pi$, or

$$N = \sqrt{-U + \sqrt{U^2 + \Omega^2}} = i\pi$$

Because

$$U = \frac{Tl^2}{2EI} \quad \text{and} \quad \Omega = \omega l^2 \sqrt{\frac{m}{EI}}$$

the expression for N leads to the exact expression for the frequency of vibration of the tensile simply supported beam

$$\omega_i = \frac{i^2 \pi^2}{l^2} \sqrt{\frac{EI}{m}} \sqrt{1 + \frac{T}{EI^2 \pi^2} \frac{l^2}{l^2}}$$

Example. Find the frequencies of vibration for a clamped-pinned tensile beam, if $T/T_E = 0.3$.

Solution. The frequency equation is

$$M \cosh M \sin N - N \sinh M \cos N = 0$$

The first Euler critical force $T_E = \frac{\pi^2 EI}{(0.7l)^2}$, so the parameter

$$U = \frac{tl^2}{2EI} = 0.3T_E \frac{l^2}{2EI} = 3.0201$$

and the frequency equation becomes

$$\begin{aligned} & \frac{\sqrt{3.0201 + \sqrt{3.0201^2 + \Omega^2}}}{\sqrt{-3.0201 + \sqrt{3.0201^2 + \Omega^2}}} \tan\left(\sqrt{-3.0201 + \sqrt{3.0201^2 + \Omega^2}}\right) \\ & - \tanh\left(\sqrt{3.0201 + \sqrt{3.0201^2 + \Omega^2}}\right) = 0 \end{aligned}$$

The root of this equation is $\Omega = \omega l^2 \sqrt{\frac{m}{EI}} = 17.519$, so the fundamental frequency of vibration of a tensile clamped-pinned beam equals

$$\omega = \frac{17.519}{l^2} \sqrt{\frac{EI}{m}} = \frac{4.1845^2}{l^2} \sqrt{\frac{EI}{m}}$$

If $T = 0$, then $\omega = \frac{3.9266^2}{l^2} \sqrt{\frac{EI}{m}}$.

Parameters

$$M = \sqrt{3.0201 + \sqrt{3.0201^2 + \Omega^2}} = 4.5604$$

$$N = \sqrt{-3.0201 + \sqrt{3.0201^2 + \Omega^2}} = 3.84152$$

The mode shape coefficients are (Table 10.7)

$$C_1 = 1, \quad C_2 = -\tanh M = -0.99978,$$

$$C_3 = -\frac{M}{N} = -1.1871, \quad C_4 = \frac{M}{N} \tan N = 0.99973$$

The modal displacement and slope

$$\begin{aligned} X(x) = X(l\xi) &= \sinh 4.5604\xi - 0.99978 \cosh 4.5604\xi - 1.1871 \sin 3.84152\xi \\ &+ 0.99973 \cos 3.84152\xi \end{aligned}$$

$$\begin{aligned} X'(l\xi) &= 4.5604 \cosh 4.5604\xi - 4.5593 \sinh 4.5064\xi - 4.56026 \cos 3.84152\xi \\ &- 3.84048 \sin 3.84152\xi \end{aligned}$$

Sliding-sliding	$\frac{i^2 \pi^2}{2}$	$\frac{\pi^2 EI}{l^2}$	$i^2 \pi^2$	$\Omega^* = \sqrt{1+U^*}$	0	0	0	1

U_{mi} is the exact critical buckling load parameter in the i th mode.
 P_{cr} is the exact critical load in the first mode.

Control. At the left clamped end

$$X(0) = -0.99978 + 0.99973 \approx 0$$

$$X'(0) = 4.5604 - 4.5602 \approx 0$$

At the right pinned end

$$X(l) = 47.80563 - 47.80557 + 0.76468 - 0.76468 \approx 0$$

10.4.3 Mode shape coefficients

Exact expressions for mode shape coefficients for a beam with different boundary conditions under axial tensile load are presented in Table 10.7.

10.4.4 Mode shape coefficients. The case of a large U

The frequency equation and expressions for mode shape coefficients for a beam with different boundary conditions may be simplified if the dimensionless tension parameter U is greater than about 12. The approximate frequency equations are presented in Table 10.8 (Bokaian, 1990). Additional dimensionless parameters

$$\alpha = \frac{\Omega}{U}, \quad \delta = -1 + \sqrt{1 + \frac{\Omega^2}{U^2}}$$

Example. Find a value of tensile load T that acts on the clamped–pinned beam so that parameter U would be so big it would be possible to use the approximate results presented in Table 10.8.

Solution. Let $T/T_E = k$, where k is unknown. Parameter

$$U = \frac{Tl^2}{2EI} = kT_E \frac{l^2}{2EI} = k \frac{\pi^2 EI}{(0.7l)^2} \frac{l^2}{2EI} = k \times 10.07$$

So parameter U equals 12 (the case of large U) starting from $k = T/T_E = 1.2$.

Example. Compare the frequency of vibration and mode shape coefficients for the clamped–pinned beam by using exact and approximate formulas; parameter $U = 12$.

Solution

Exact solution. Parameters M and N are

$$M = \sqrt{U + \sqrt{U^2 + \Omega^2}} = \sqrt{12 + \sqrt{144 + \Omega^2}}$$

$$N = \sqrt{-U + \sqrt{U^2 + \Omega^2}} = \sqrt{-12 + \sqrt{144 + \Omega^2}}$$

The frequency equation (Table 10.6) is

$$\frac{M}{N} \tan N - \tanh M = 0$$

The root of this equation is $\Omega = 22.572$, which leads to parameters

$$M = \sqrt{12 + \sqrt{144 + \Omega^2}} = 6.1289$$

$$N = \sqrt{-12 + \sqrt{144 + \Omega^2}} = 3.6828$$

TABLE 10.8 Uniform one-span beams with different boundary conditions under tensile axial load: approximate frequency equations and mode shape coefficients for tension parameter $U > 12$

Beam type	Frequency equation	Mode shape coefficients			
		C_1	C_2	C_3	C_4
Free-free	$\left[\tan^{-1} \left(-\frac{\alpha^3}{4 + 3\alpha^2} \right) + (i+1)\pi \right]^2 = U\delta$	1	-1	$\frac{N}{M}$	$-\frac{M^2}{N^2}$
Sliding-free	$\tan \sqrt{U\delta} = -\frac{\delta^3}{\alpha^3}$	-	-	-	-
Clamped-free	$\tan \sqrt{U\delta} = -\frac{2 + \alpha^2}{\alpha}$	1	-1	$-\frac{M}{N}$	1
Pinned-free	$\tan \sqrt{U\delta} = \frac{\alpha^3}{\delta^3}$	-	-	-	-
Pinned-pinned	$\sin N = 0^\dagger$	0	0	1	0
Clamped-pinned	$\tan \sqrt{U\delta} = \frac{\delta}{\alpha}$	1	-1	$-\frac{M}{N}$	$\frac{M}{N} \tan N$
Clamped-clamped	$\tan \sqrt{U\delta} = \alpha$	1	-1	$-\frac{M}{N}$	-1
Clamped-sliding	$\tan \sqrt{U\delta} = \frac{\delta}{\alpha}$	1	-1	$-\frac{M}{N}$	1
Sliding-pinned	$\cos N = 0^\dagger$	0	0	0	1
Sliding-sliding	$\sin N = 0^\dagger$	0	0	0	1

[†]Approximate and exact frequency vibrations coincide (Table 10.6).

The mode shape coefficients are (Table 10.7)

$$C_1 = 1, \quad C_2 = -\tanh M = -0.99999$$

$$C_3 = -\frac{M}{N} = -1.6642, \quad C_4 = \frac{M}{N} \tan N = 1.00030$$

Approximate solution. The frequency equation (Table 10.7)

$$\tan \sqrt{U\delta} = \frac{U}{\Omega} \left(-1 + \sqrt{1 + \frac{\Omega^2}{U^2}} \right)$$

or

$$\tan \sqrt{12 \left(-1 + \sqrt{1 + \frac{\Omega^2}{144}} \right) + \frac{12}{\Omega} \left(1 - \sqrt{1 + \frac{\Omega^2}{144}} \right)} = 0$$

The root of this equation is $\Omega = 22.569$. Parameters M , N and mode shape coefficients practically coincide with results that were obtained by using exact formulas.

10.4.5 Upper and lower bound approximation to the frequency of vibration

Table 10.9 gives the upper and lower bound approximation to the frequency of vibration of tensile beams with different boundary conditions. The parameters Ω^* , Ω are given in terms of tension parameter U (Bokaian, 1990).

$$U = Tl^2/2EI, \quad \Omega = \omega l^2/\alpha, \quad \alpha^2 = EI/\rho A, \quad U^* = T/T_E,$$

$$\Omega^* = \Omega/\Omega_0, \quad \Omega^* = (1 + \gamma U^*)^{1/2}$$

Example. Find the fundamental frequency of vibration for a pinned-pinned tensile beam.

Solution. The value of a dimensionless natural frequency parameter is

$$\Omega = \sqrt{2\pi i}\sqrt{U}, \quad \text{so} \quad \omega l^2 \sqrt{\frac{m}{EI}} = \sqrt{2\pi i} \sqrt{\frac{Tl^2}{2EI}}$$

The frequency of vibration is $\omega = \frac{\pi i}{l} \sqrt{\frac{T}{m}}$. This formula coincides with the exact expression for the frequency of transversal vibration of the string for which $\omega = \sqrt{\frac{T}{m}}k$, where the wavenumber $kl = \pi i$ (Crawford, 1976).

The upper bound value for the normalized natural frequency parameter Ω^* in terms of normalized tension parameter U^* is $\Omega^* = \sqrt{1 + U^*}$, so

$$\Omega^* = \frac{\omega}{\omega_0} = \sqrt{1 + \frac{Tl^2}{\pi^2 EI}}$$

which leads to

$$\omega = \frac{\pi^2}{l^2} \sqrt{\frac{EI}{m}} \sqrt{1 + \frac{Tl^2}{\pi^2 EI}}$$

Example. Find the upper bound value for the fundamental frequency of vibration of a clamped-pinned beam. Parameter $T/T_E = 1.1915$; in this case parameter $U = 12$.

Solution. The upper bound value for

$$\Omega^* = \sqrt{1 + 0.978U^*} = \sqrt{1 + 0.978 \times 1.1915} = 1.47149$$

TABLE 10.9. Uniform one-span beams with different boundary conditions under tensile axial load: upper and lower bounds of frequency parameters

Beam type	Value of Ω for lower modes ($i = 1, 2, 3 \dots$)	γ	Upper bound value for Ω^* (The Rayleigh quotient)	Lower bound value for Ω ($i = 1$)
Free-free	$(i + 1)\pi\sqrt{2U}$	0.975	$\sqrt{1 + 0.975U^*}$	$2\sqrt{2}\pi\sqrt{U}$
Sliding-free	$\pi i\sqrt{2U}$	0.925	$\sqrt{1 + 0.925U^*}$	$\sqrt{2}\pi\sqrt{U}$

Clamped-clamped	$\frac{2\pi iU}{\sqrt{2U - 2}} \approx \pi i\sqrt{2U}$	0.97	$\sqrt{1 + 0.97U^*}$	$\sqrt{2}\pi\sqrt{U}$
Clamped-sliding	$\frac{\pi}{\sqrt{2}}(2i - 1)\sqrt{U}$	0.97	$\sqrt{1 + 0.97U^*}$	$\frac{\pi}{\sqrt{2}}\sqrt{U}$
Sliding-pinned	$\pi i\sqrt{2U}$	1.0	$\sqrt{1 + U^*}^\dagger$	—
Sliding-sliding	$\pi i\sqrt{2U}$	1.0	$\sqrt{1 + U^*}^\dagger$	—

A tensile force has the effect of increasing the frequency of vibration.

The extensive numerical results and their discussion for beams with different boundary conditions are presented by Bokaian (1990).

[†]These expressions are exact.

So the frequency of vibration of the beam under tensile load is $\omega = 1.47149\omega_0$, where $\omega_0 = \frac{3.9266^2}{l^2} \sqrt{\frac{EI}{m}}$ is the frequency of vibration of the beam without tensile load.

So the parameter λ^2 for the upper bound value for the fundamental frequency of vibration equals $3.9266^2 \times 1.47149 = 22.68771$.

The exact value is 22.572.

10.5 VERTICAL CANTILEVER BEAMS. THE EFFECT OF SELF-WEIGHT

This section contains the frequency parameter λ for the transversal vibration of a Bernoulli–Euler vertical uniform cantilever beam, with account taken of the effect of self-weight. The axial tension at coordinate x is $T(x) = mg(l - x)$; the gravity parameter and frequency of vibration are

$$\gamma = \frac{mgl^3}{EI}, \quad \omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$$

Squared frequency parameters λ^2 for clamped–free (CL-FR) and pin-guided–clamped (PG-CL) beams are presented in Table 10.10 (Naguleswaran, 1991).

The critical gravity parameter γ (natural frequency is equal to zero) for standing (CL-FR) and (PG-CL) beams is shown in Table 10.11.

10.6 GAUGE FACTOR

The gauge factor, G_{Nn} , describes the sensitivity of the beam as a gauge, vibrating at $\omega = \omega_n$ to changes in the axial force N in the vicinity of the operating force T_0 .

Static linearity. The axial force is a result of an external effect on the beam

$$G_{Nn} = \left[\frac{1}{\omega_n} \frac{\partial \omega}{\partial T} \right]_{T=T_0} \quad (10.17)$$

For a beam with rectangular cross-section

$$G_{Nn} = \frac{1}{2} \frac{\gamma_n \frac{1-v^2}{Ebh} \left(\frac{l}{h}\right)^2}{1 + \gamma_n \varepsilon_0 (1-v^2) \left(\frac{l}{h}\right)^2} \quad (10.18)$$

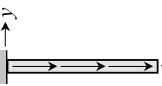

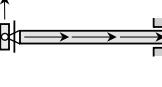

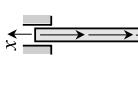

Static nonlinearity. The axial force is a result of an axial elongation of the beam caused by vibration (Chapter 12.1.1). In this case, it is more useful to define a gauge factor G_{en} , describing the sensitivity of mode n to changes in the strain ε in the vicinity of the operating point $\varepsilon_0 = (1-v)\sigma_0/E$

$$G_{en} = \left[\frac{1}{\omega_n} \frac{\partial \omega_n}{\partial \varepsilon} \right]_{\varepsilon=\varepsilon_0} \quad (10.19)$$

For a beam with rectangular cross-section

$$G_{en} = \frac{1}{2} \frac{\gamma_n (1-v^2) \left(\frac{l}{h}\right)^2}{1 + \gamma_n \varepsilon_0 (1-v^2) \left(\frac{l}{h}\right)^2} \quad (10.20)$$

TABLE 10.11. The critical gravity parameters

Standing clamped-free beam mode			Standing pin-guided-clamped beam mode		
1	2	3	1	2	3
7.837347	55.97743	148.5083	3.476597	44.13849	129.25843

In both cases, the coefficient

$$\gamma_n = \frac{12}{l^2} \frac{\int_0^l [X'_n(x)]^2 dx}{\int_0^l [X''_n(x)]^2 dx}$$

where $X_n(x)$ is the shape function for a particular mode n . Integrals in the formula for γ are presented in Table 5.6.

The analytical expression for the gauge factor considering the effects of lateral deformation

$$G_{en} = -(2 + v) + \frac{1}{2}[1 + 2\varepsilon_0(1 + v)] \frac{\gamma_n(1 - v^2)\left(\frac{l}{h}\right)^2}{1 + \gamma_n\varepsilon_0(1 - v^2)\left(\frac{l}{h}\right)^2} \quad (10.21)$$

Numerical results

Clamped-clamped beam, Static nonlinearity. The gauge factor G of the fundamental mode as a function of the residual tensile strain ε_0 is presented in Fig. 10.8 (Tilmans, 1993)

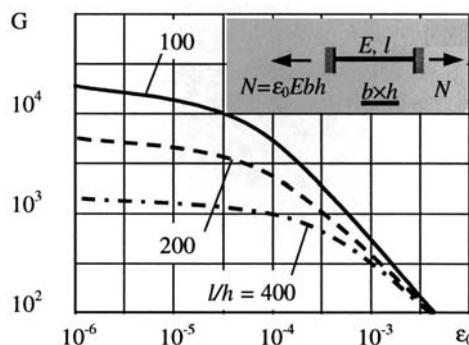

FIGURE 10.8. Gauge factor G of the fundamental mode of vibration for a clamped-clamped beam for three values of the slenderness ratio I/h ; a cross-section of the beam is rectangular, the width is b , height is h , $b > h$; and the Poisson ratio of material $v = 0.3$.

The gauge factors for a cantilever beam with a lumped mass and for a simply supported beam with a symmetrical distributed mass are studied by Lebed *et al.* (1996a and b).

PRISMATIC BEAMS UNDER COMPRESSIVE AND TENSILE AXIAL LOADS

CHAPTER 11

BRESS-TIMOSHENKO UNIFORM PRISMATIC BEAMS

Chapter 11 focuses on uniform Bress-Timoshenko beams. Eigenvalues and eigenfunctions for beams with a classical boundary conditions are presented.

NOTATION

A	Cross-sectional area of the beam
E, G	Modulus of elasticity and modulus of rigidity of the beam material
EI	Bending stiffness
r_0	Radius of gyration of a cross-sectional area of the beam
I	Moment of inertia of a cross-sectional area of the beam
k	Shear coefficient
l	Length of the beam
R	Correction factor
s	Notation of stiffness coefficients
$s(M\psi)$	Flexural stiffness coefficient of moment due to rotational deformation
$s(MX)$	Flexural stiffness coefficient of moment due to transverse deformation
$s(V\psi)$	Flexural stiffness coefficient of shear due to rotational deformation
$s(VX)$	Flexural stiffness coefficient of shear due to transverse deformation
t	Time
$v_1 v_2$	Velocities of propagation of the waves
Q, M	Shear force and bending moment
x	Spatial coordinate
x, y, z	Cartesian coordinates
$X(x)\psi(x)$	Mode shape
$y(x, t), \psi(x, t)$	Lateral displacement of the beam
ν	Poisson coefficient
ρ, m	Density of material and mass per unit length of beam, $m = \rho A$
ω	Circular natural frequency of the transverse vibration of the beam

11.1 FUNDAMENTAL RELATIONSHIPS

11.1.1 Differential equations

The Bress–Timoshenko theory is used for describing the vibration of thick beams and for calculation of higher frequencies of vibrations. Timoshenko's equation is called the wave equation of the transverse vibration of a beam.

The slope of the deflection curve (DC) depends not only on the rotation of the cross-sections of the beam but also on the shearing deformations. Love and Bress–Timoshenko theories take into account the effects of rotatory inertia and shearing force (Chapter 1) (Timoshenko, 1922; Weaver *et al.* 1990). The free-body diagram of an element of a Timoshenko beam theory is presented in Fig. 11.1.

The lines n and τ denote the normal to the face $a - b$ and the tangent to the deflection curve; subscripts BE and T denotes the Bernoulli–Euler and Timoshenko theories, respectively. If the shear deformation is neglected, the tangent to the deflection curve τ coincides with the normal to the face $a - b$ (Bernoulli–Euler theory). The angle ψ denotes the slope of the deflection curve due to bending deformation alone, e.g. when the shearing force is neglected; the angle β between the tangent to the deflection curve and the normal to the face denotes the shear deformation of the element (shear angle). Due to shear deformation, the tangent to the deflection curve will not be perpendicular to the face $a - b$.

The total slope, bending moment and shear force are

$$\begin{aligned}\frac{dy}{dx} &= \psi + \beta \\ M &= -EI \frac{d\psi}{dx} \\ Q &= k\beta AG = kAG \left(\frac{dy}{dx} - \psi \right)\end{aligned}\quad (11.1)$$

where k is a shear coefficient depending on the shape of the cross-section, and G is the modulus of elasticity in the shear. Shear coefficients for different cross-sections are presented in Section 9.1.4.

The higher order theories (Heyliger and Reddy, 1988; Stephen, 1978, 1983; Levinson 1981, 1982; Stephen and Levinson, 1979; Bickford, 1982; Murty, 1985; Ewing, 1990)

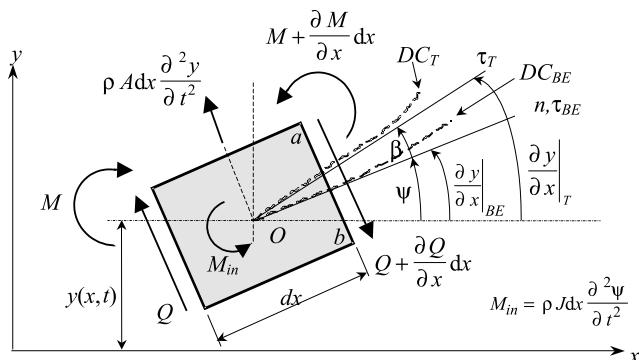

FIGURE 11.1 Notation and geometry of an element of a Timoshenko beam.

correctly account for the stress-free conditions on the upper and lower surfaces of the beam. In this case the need for a shear correction coefficient is eliminated.

Timoshenko equations. First form – coupled equations

$$\begin{aligned} EI \frac{\partial^2 y}{\partial x^2} + kAG \left(\frac{\partial y}{\partial x} - \psi \right) - \rho I \frac{\partial^2 \psi}{\partial t^2} &= 0 \\ kAG \left(\frac{\partial^2 y}{\partial x^2} - \frac{\partial \psi}{\partial x} \right) - \rho A \frac{\partial^2 \psi}{\partial t^2} &= 0 \end{aligned} \quad (11.2)$$

The shear coefficient k for various cross sections is presented in Table 11.1.

Timoshenko complete equations. Second form – separated equations
(Cheng, 1970)

The equation with respect to the transverse displacement y may be written as follows

$$EI \frac{\partial^4 y}{\partial x^4} + \rho A \frac{\partial^2 y}{\partial t^2} - \rho I \left(1 + \frac{E}{kG} \right) \frac{\partial^4 y}{\partial x^2 \partial t^2} + \frac{\rho^2 I}{kG} \frac{\partial^4 y}{\partial t^4} = 0 \quad (11.3)$$

The equation with respect to bending slope ψ

$$EI \frac{\partial^4 \psi}{\partial x^4} + \rho A \frac{\partial^2 \psi}{\partial t^2} - \rho I \left(1 + \frac{E}{kG} \right) \frac{\partial^4 \psi}{\partial x^2 \partial t^2} + \frac{\rho^2 I}{kG} \frac{\partial^4 \psi}{\partial t^4} = 0 \quad (11.3a)$$

The Timoshenko equation describes the disturbance of propagation in the axial direction of two waves with velocities $v_1 = \sqrt{\frac{E}{\rho}}$ and $v_2 = \sqrt{\frac{kG}{\rho}}$.

11.1.2 Kinetic and potential energy (Bolotin, 1978; Yokoyama, 1991)

Kinetic energy

$$T = \frac{1}{2} \int_0^l m(x) \left(\frac{\partial y}{\partial t} \right)^2 dx + \frac{1}{2} \int_0^l \rho I \left(\frac{\partial^2 y}{\partial x \partial t} - \frac{\partial \beta}{\partial t} \right)^2 dx \quad (11.4)$$

Potential energy

$$I = \frac{1}{2} \int_0^l EI \left(\frac{\partial^2 y}{\partial x^2} - \frac{\partial \beta}{\partial x} \right)^2 dx + \frac{1}{2} \int_0^l kGA \left(\frac{\partial y}{\partial x} - \psi \right)^2 dx + \frac{1}{2} \int_0^l k_{tr} y^2 dx + \frac{1}{2} \int_0^l k_G \left(\frac{\partial y}{\partial x} \right)^2 dx \quad (11.5)$$

where y = total transversal deflection

ψ = slope of the deflecting curve due to bending deformation alone

k_{tr} = Winkler foundation modulus

k_G = shear foundation modulus

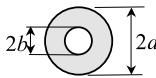

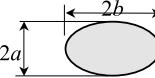

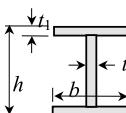

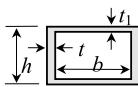

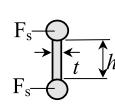

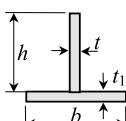

k = shear coefficient

β = shear angle

The work W done by a compressive axial force N (positive for tension) is

$$W = -N \int_0^l \frac{1}{2} \left(\frac{\partial y}{\partial x} \right)^2 dx \quad (11.6)$$

TABLE 11.1. Shear coefficients for various cross-sections (Love, 1927; Cowper, 1996)

Cross-section	Coefficient k
Circle	 $\frac{6(1+v)}{7+6v}$
Hollow circle	 $\frac{6(1+v)(1+m^2)^2}{(7+6v)(1+m^2)^2 + (20+12v)m^2}, m = \frac{b}{a}$
Rectangular	 $\frac{10(1+v)}{12+11v}$
Ellipse	 $\frac{12(1+v)a^2(3a^2+b^2)}{(40+37v)a^4 + (16+10v)a^2b^2 + vb^4}$
Semicircle	 $\frac{1+v}{1.305+1.273v}$
Thin walled round tube	 $\frac{2(1+v)}{4+3v}$
Thin walled square tube	 $\frac{20(1+v)}{48+39v}$
Thin-walled I-section	 $\frac{10(1+v)(1+3m)^2}{M_1 + vM_2 + 5mn^2[6(1+m) + v(8+9m)]}, m = \frac{2bt_f}{ht_w}, n = \frac{b}{h}$ $M_1 = 12 + 72m + 150m^2 + 90m^3, M_2 = 11 + 66m + 135m^2 + 90m^3$
Thin-walled box section	 $\frac{10(1+v)(1+3m)^2}{M_1 + vM_2 + 10mn^2(3+v+3m)}, m = \frac{bt_1}{ht}; n = \frac{b}{h}$
Spar-and-web section	 $\frac{10(1+v)(1+3m)^2}{M_1 + vM_2}, m = \frac{2F_s}{ht}, F_s \text{ is area of one spar}$
Thin-walled T-section	 $\frac{10(1+v)(1+4m)^2}{M_3 + vM_4 + 10mn^2(1+m)[3+(1+4m)]}, m = \frac{bt_1}{ht}, n = \frac{b}{h}$ $M_3 = 12 + 96m + 276m^2 + 192m^3, M_4 = 11 + 88m + 248m^2 + 216m$

11.2 ANALYTICAL SOLUTION

11.2.1 Frequency and normal mode equations

The differential equations of the transverse vibration of uniform beams are

$$\begin{aligned} EI \frac{\partial^4 y}{\partial x^4} + \frac{\gamma A}{g} \frac{\partial^2 y}{\partial t^2} - \left(\frac{\gamma I}{g} + \frac{EI\gamma}{kgG} \right) \frac{\partial^4 y}{\partial x^2 \partial t^2} + \frac{\gamma I}{g} \frac{\gamma}{kgG} \frac{\partial^4 y}{\partial t^4} &= 0 \\ EI \frac{\partial^4 \psi}{\partial x^4} + \frac{\gamma A}{g} \frac{\partial^2 \psi}{\partial t^2} - \left(\frac{\gamma I}{g} + \frac{EI\gamma}{kgG} \right) \frac{\partial^4 \psi}{\partial x^2 \partial t^2} + \frac{\gamma I}{g} \frac{\gamma}{kgG} \frac{\partial^4 \psi}{\partial t^4} &= 0 \end{aligned} \quad (11.7)$$

where y , ψ and $\frac{\partial y}{\partial x}$ are the transversal displacement, bending and total slope, respectively.

The shear slope, bending moment and shear force are

$$\begin{aligned} \beta &= \frac{\partial y}{\partial x} - \psi \\ M &= -EI \frac{\partial \psi}{\partial x} \\ Q &= k \left(\frac{\partial}{\partial x} - \psi \right) AG \end{aligned}$$

Solution

$$y = X(x)e^{j\omega t} \quad \text{and} \quad \psi = \Psi e^{j\omega t}$$

Equations for normal functions of X and Ψ are (Huang, 1961)

$$\begin{aligned} X^{1V} + b^2(r^2 + s^2)X'' - b^2(1 - b^2r^2s^2)X &= 0 \\ \Psi^{1V} + b^2(r^2 + s^2)\Psi'' - b^2(1 - b^2r^2s^2)\Psi &= 0 \end{aligned} \quad (11.8)$$

$$b^2 = \frac{mL^4}{EI}\omega^2 \quad r^2 = \frac{I}{Al^2} \quad s^2 = \frac{EI}{kAGl^2} \quad m = \rho A, \rho = \frac{\gamma}{g}$$

where r is the dimensionless radius of gyration.

Eigenvalues. The frequencies of vibration may be calculated by the formula

$$\omega = \frac{b}{l^2} \sqrt{\frac{EI}{m}}$$

It is necessary to differentiate two cases.

Case 1. This case would correspond to lower frequency vibrations

$$\sqrt{(r^2 - s^2)^2 + \frac{4}{b^2}} > (r^2 + s^2) \quad \text{or} \quad b^2r^2s^2 = \frac{m\omega^2 I}{kA^2 G} < 1 \quad (11.9)$$

Case 2. This case would correspond to higher frequency vibrations

$$\sqrt{(r^2 - s^2)^2 + \frac{4}{b^2}} < (r^2 + s^2) \quad \text{or} \quad b^2 r^2 s^2 = \frac{m\omega^2 I}{kA^2 G} > 1 \quad (11.10)$$

Eigenfunctions. Let

$$\begin{aligned} \begin{pmatrix} \alpha \\ \beta \end{pmatrix} &= \frac{1}{\sqrt{2}} \sqrt{\mp(r^2 + s^2) + \sqrt{(r^2 - s^2)^2 + \frac{4}{b^2}}} \quad \text{for case 1} \\ \alpha &= j\alpha' = \frac{j}{\sqrt{2}} \sqrt{(r^2 + s^2) - \sqrt{(r^2 - s^2)^2 + \frac{4}{b^2}}} \quad j^2 = -1 \quad \text{for case 2} \end{aligned}$$

Parameter β for cases 1 and 2 are the same.

Case 1 (α is a real number, i.e. $b^2 r^2 s^2 < 1$)

$$\begin{aligned} X(\xi) &= C_1 \cosh b\alpha\xi + C_2 \sinh b\alpha\xi + C_3 \cos b\alpha\xi + C_4 \sin b\alpha\xi, \quad \xi = x/l \\ \Psi &= C'_1 \sinh b\alpha\xi + C'_2 \cosh b\alpha\xi + C'_3 \sin b\alpha\xi + C'_4 \cos b\alpha\xi \end{aligned} \quad (11.11)$$

Case 2 (α is an imaginary number, i.e. $b^2 r^2 s^2 > 1$)

$$\begin{aligned} X(\xi) &= C_1 \cosh b\alpha'\xi + jC_2 \sinh b\alpha'\xi + C_3 \cos b\beta\xi + C_4 \sin b\beta\xi, \quad \xi = x/l \\ \Psi &= jC'_1 \sin b\alpha\xi + C'_2 \cos b\alpha\xi + C'_3 \sin b\beta\xi + C'_4 \cos b\beta\xi \end{aligned} \quad (11.12)$$

Only one half of the constants are independent. They are related as follows:

$$\begin{aligned} C_1 &= \frac{l}{b\alpha} [1 - b^2 s^2 (\alpha^2 + r^2)] C'_1 & C'_1 &= \frac{b\alpha^2 + s^2}{l} C_1 \\ C_2 &= \frac{l}{b\alpha} [1 - b^2 s^2 (\alpha^2 + r^2)] C'_2 & C'_2 &= \frac{b\alpha^2 + s^2}{l} C_2 \\ C_3 &= -\frac{l}{b\beta} [1 + b^2 s^2 (\beta^2 - r^2)] C'_2 & \text{or} & C'_3 = -\frac{b\beta^2 - s^2}{l} C_3 \\ C_4 &= \frac{l}{b\beta} [1 + b^2 s^2 (\beta^2 - r^2)] C'_4 & C'_4 &= \frac{b\beta^2 - s^2}{l} C_4 \end{aligned}$$

The orthogonality condition of normal functions for the m th and n th modes

$$\int_0^1 (X_m X_n + r_0^2 \psi_m \psi_n) d\xi = 0, \quad m \neq n,$$

where r_0 is the radius of gyration of the cross-section around the principal axis, $r_0 = \sqrt{\frac{I}{A}}$.

The frequency equation and normal modes for a beam with classical boundary conditions are presented in Tables 11.2 and 11.3. Additional notation:

$$\lambda = \frac{\alpha}{\beta} \quad \text{for case 1; and} \quad \lambda' = \frac{\alpha'}{\beta} \quad \text{for case 2;}$$

$$\zeta = \frac{\alpha^2 + r^2}{\alpha^2 + s^2} = \frac{\beta^2 - s^2}{\beta^2 - r^2} = \frac{\alpha^2 + r^2}{\beta^2 - r^2} = \frac{\beta^2 - s^2}{\alpha^2 + s^2} \quad \text{for both cases}$$

Pinned-free	$\lambda' \tan b\alpha' - \zeta \tan b\beta = 0$	$X = -\lambda' \frac{\cos b\beta}{\cosh b\alpha'} \sin b\alpha'\xi + \sin b\beta\xi$ $\psi = -\frac{1}{\lambda' \sinh b\alpha'} \cos b\alpha'\xi + \cos b\beta\xi$	

Special case (Bernoulli–Euler theory). In this case $r = 0, s = 0$ and

$$\alpha = \beta = \frac{1}{\sqrt{b}}, \quad \lambda = \frac{\alpha}{\beta} = 1, \quad \lambda' = \frac{\alpha'}{\beta} = j, \quad \zeta = \frac{\alpha^2 + r^2}{\beta^2 - r^2} = \frac{\beta^2 - s^2}{\alpha^2 + s^2} = 1.$$

Example. For a pinned–free beam the frequency equations for cases 1 and 2 are

$$\begin{aligned}\lambda \tanh b\alpha - \zeta \tan b\beta &= 0 \\ \lambda' \tan b\alpha' + \zeta \tan b\beta &= 0\end{aligned}$$

In both cases, the frequency equations reduce to

$$\tanh \sqrt{b} - \tan \sqrt{b} = 0$$

Solution of equation 11.8. The expression for the normal function may be presented as follows

$$X(\xi) = A_1 \sinh b\alpha\xi + A_2 \cosh b\alpha\xi + A_3 \sin b\beta\xi + A_4 \cos b\beta\xi$$

or, by using special functions, such as Krylov's functions

$$X(\xi) = A_1 X_1(\xi) + A_2 X_2(\xi) + A_3 X_3(\xi) + A_4 X_4(\xi)$$

where

$$\begin{aligned}X_1(\xi) &= \frac{1}{b^2(\alpha^2 + \beta^2)} (b^2 \alpha^2 \cosh jb\beta\xi + b^2 \beta^2 \cosh b\alpha\xi) \\ X_2(\xi) &= \frac{1}{b^2(\alpha^2 + \beta^2)} \left(-\frac{jb\alpha^2}{\beta} \sinh jb\beta\xi + \frac{b\beta^2}{\alpha} \sinh b\alpha\xi \right) \\ X_3(\xi) &= \frac{1}{b^2(\alpha^2 + \beta^2)} (\cosh b\alpha\xi - \cosh jb\beta\xi) \\ X_4(\xi) &= \frac{1}{b^2(\alpha^2 + \beta^2)} \left(\frac{1}{b\alpha} \sinh b\alpha\xi + \frac{j}{b\beta} \sinh jb\beta\xi \right) \\ \begin{pmatrix} \alpha \\ \beta \end{pmatrix} &= \frac{1}{\sqrt{2}} \sqrt{\mp(r^2 + s^2) + \sqrt{(r^2 - s^2)^2 + \frac{4}{b^2}}}\end{aligned}$$

Fundamental functions and their derivatives result in the unit matrix at $\xi = 0$ (Chapter 4).

Special case. For the Bernoulli–Euler theory, the parameters are

$$s = r = 0, \quad \alpha = \beta = \sqrt{\frac{1}{b}} = \frac{1}{\lambda}, \quad \lambda^4 = \frac{\omega^2 m l^4}{EI}$$

and functions X_i transfer to Krylov functions (Section 4.2).

11.2.2 State matrix. Dynamic stiffness matrix

The dynamic stiffness coefficients are presented as non-dimensional parameters corresponding to the effects of rotary inertia and of bending and shear deformation. The beam element and positive directions for the bending moment M , shear force Q , normal functions X and ψ are presented in Fig. 11.2.

Conditions matrix (Cheng, 1970)

$$\begin{bmatrix} X(\xi) \\ \psi(\xi) \\ Q(\xi) \\ M(\xi) \end{bmatrix} = A \times \begin{bmatrix} C_1 \\ C_2 \\ C_3 \\ C_4 \end{bmatrix} \quad (11.13)$$

where the matrix of the system is

$$A = \begin{bmatrix} \cosh b\alpha\xi & \sinh b\alpha\xi \\ T \sinh b\alpha\xi & T \cosh b\alpha\xi \\ (\mu - kGAT) \sinh b\alpha\xi & (\mu - kGAT) \cosh b\alpha\xi \\ -\Omega \cosh b\alpha\xi & -\Omega \sinh b\alpha\xi \end{bmatrix} \begin{bmatrix} \cos b\beta\xi & \sin b\beta\xi \\ -U' \sin b\beta\xi & U' \cos b\beta\xi \\ (-\eta + kAGU') \sin b\beta\xi & (\eta - kAGU') \cos b\beta\xi \\ \tau' \cos b\beta\xi & \tau' \sin b\beta\xi \end{bmatrix}$$

Parameters b, r, s, α, β are presented in Section 11.2.1. Additional parameters are

$$\begin{aligned} T &= \frac{b\alpha^2 + s^2}{l} & \mu &= kaG \frac{\alpha b}{l} & \eta &= kAG \frac{\beta b}{l} \\ \Omega &= EI \frac{\alpha b}{l} T & \tau' &= EI \frac{\beta b}{l} U' & U' &= \frac{b\beta^2 - s^2}{l} \end{aligned}$$

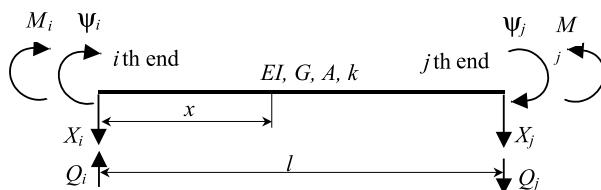

FIGURE 11.2. Timoshenko beam, positive notation.

The vector of integration constants may be presented in terms of initial parameters as follows

$$\begin{bmatrix} C_1 \\ C_2 \\ C_3 \\ C_4 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 1 & 0 \\ 0 & T & 0 & U' \\ 0 & (\mu - kGAT) & 0 & (\eta - kAGU') \\ -\Omega & 0 & \tau' & 0 \end{bmatrix}^{-1} \times \begin{bmatrix} Y(0) \\ \psi(0) \\ Q(0) \\ M(0) \end{bmatrix}$$

Dynamic stiffness matrix

$$\begin{bmatrix} M_i \\ M_j \\ Q_i \\ Q_j \end{bmatrix} = \begin{bmatrix} s(M\psi)_1 & s(M\psi)_2 & s(MX)_1 & s(MX)_2 \\ & s(M\psi)_1 & s(MX)_2 & s(MX)_1 \\ & & s(QX)_1 & s(QX)_2 \\ \text{Symmetric} & & & s(QX)_1 \end{bmatrix} \times \begin{bmatrix} \psi_i \\ \psi_j \\ X_i \\ X_j \end{bmatrix} \quad (11.14)$$

The elements of the dynamic stiffness matrix for cases 1 and 2 are as follows (Cheng, 1970).

Case 1. $b^2r^2s^2 < 1$

$$\begin{aligned} s(M\psi)_1 &= \frac{l[-\alpha(\beta^2 - s^2) \sinh b\alpha \cos b\beta + \beta(\alpha^2 + s^2) \cosh b\alpha \sin b\beta]}{kAGbs^2(\alpha^2 + \beta^2)D} \\ s(M\psi)_2 &= \frac{l[\alpha(\beta^2 - s^2) \sinh b\alpha - \beta(\alpha^2 + s^2) \sin b\beta]}{kAGbs^2(\alpha^2 + \beta^2)D} \\ s(MX)_1 &= \frac{l^2[\alpha\beta(2s^2 + \alpha^2 - \beta^2)(1 - \cosh b\alpha \cos b\beta) - (2\alpha^2\beta^2 - \alpha^2s^2 + \beta^2s^2) \sinh b\alpha \sin b\beta]}{EIb^2(\alpha^2 + \beta^2)^2\alpha\beta D} \\ s(MX)_2 &= \frac{(\beta^2 - s^2)(\alpha^2 + s^2)[- \cosh b\alpha + \cos b\beta]}{kAGs^2(\alpha^2 + \beta^2)D} \\ s(QX)_1 &= \frac{l[\alpha(\beta^2 - s^2) \cosh b\alpha \sin b\beta + \beta(\alpha^2 + s^2) \sinh b\alpha \cos b\beta]}{EIb\alpha\beta(\alpha^2 + \beta^2)D} \\ s(QX)_2 &= \frac{l[\beta(\alpha^2 + s^2) \sinh b\alpha + \alpha(\beta^2 - s^2) \sin b\beta]}{EIb\alpha\beta(\alpha^2 + \beta^2)D} \\ D &= \frac{l^2[2\alpha\beta(\beta^2 - s^2)(\alpha^2 + s^2) - 2\alpha\beta(\beta^2 - s^2)(\alpha^2 + s^2) \cosh b\alpha \cos b\beta + [(\alpha^2 - \beta^2)(\alpha^2\beta^2 - s^4) + 4\alpha^2\beta^2s^2] \sinh b\alpha \sin b\beta]}{kAGEIb^2(\alpha^2 + \beta^2)^2\alpha\beta s^2} \end{aligned} \quad (11.15)$$

Case 2. $b^2r^2s^2 > 1, \alpha' = j\omega$

$$\begin{aligned}
 s(M\psi)_1 &= \frac{1}{bD} [\alpha'(\beta^2 - s^2) \sin b\alpha' \cos b\beta + \beta(\alpha^2 + s^2) \sin b\beta \cos b\alpha'] \frac{EI}{l} \\
 s(M\psi)_2 &= -\frac{1}{bD} [\alpha'(\beta^2 - s^2) \sin b\alpha' + \beta(\alpha^2 + s^2) \sin b\beta] \frac{EI}{l} \\
 s(MX)_1 &= \frac{1}{(\alpha^2 + \beta^2)D} (\alpha^2 + s^2)(\beta^2 - s^2) \left[(s^2 - r^2) - \frac{s^2(s^2 + r^2) + 2\beta^2\alpha^2}{\beta\alpha'} \sin b\alpha' \sin b\beta \right] \frac{EI}{l^2} \\
 &\quad + \frac{(\alpha^2 + s^2)(\beta^2 - s^2)}{(\alpha^2 + \beta^2)D} (r^2 - s^2) \cos b\alpha' \cos b\beta \frac{EI}{l^2} \\
 s(MX)_2 &= \frac{(\alpha^2 + s^2)(\beta^2 - s^2)}{D} [\cos b\beta - \cos b\alpha'] \frac{EI}{l^2} \\
 S(QX)_1 &= \frac{1}{bD} \left[\frac{(\alpha^2 + s^2)}{\alpha'} \sin b\alpha' + \frac{(\beta^2 - s^2)}{\beta} \sin b\beta \right] \frac{EI}{l^3} \\
 S(QX)_2 &= \frac{1}{bD} \left[\frac{(\alpha^2 + s^2)}{\alpha'} \cos b\beta \sin b\alpha' + \frac{(\beta^2 - s^2)}{\beta} \sin b\beta \cos b\alpha' \right] \frac{EI}{l^3} \\
 D &= \frac{2(\alpha^2 + s^2)(\beta^2 - s^2)}{b^2(\alpha^2 + \beta^2)} [1 - \cos b\beta \cos b\alpha'] \\
 &\quad + \frac{\beta^2(\alpha + s^2)^2 + \alpha'^2(\beta^2 - s^2)^2}{\alpha'\beta b^2(\alpha^2 + \beta^2)} \sin b\beta \sin b\alpha' \tag{11.16}
 \end{aligned}$$

Another representation of the Timoshenko equation is presented in Genkin and Tarckhanov (1979).

The transitional matrix for the Timoshenko equation is presented in Ivovich (1981) and Pilkey (1994).

11.3 SOLUTIONS FOR THE SIMPLEST CASES

In this section, the results for the fundamental mode of vibration for simply supported, cantilever and clamped beams are presented.

11.3.1 Pinned-pinned beam. Frequency equation and frequency of vibration: exact solution

Truncated differential equation. In this case, the term $\frac{\partial^4 y}{\partial t^4}$ in the Timoshenko equation is omitted.

Effect of rotary motion and shearing force. Frequency equation (Filin, 1981)

$$\frac{n^2\pi^2}{l^2} \frac{m\omega^2}{EA} \left(1 + \frac{E}{kG} \right) + \frac{m\omega^2}{EI} = \frac{n^4\pi^4}{l^4} \tag{11.17}$$

Frequency of vibration

$$\omega = \frac{n^2\pi^2}{l^2} \sqrt{\frac{EI}{m}} R$$

where correction factor

$$R = \frac{1}{\sqrt{1 + \frac{n^2\pi^2}{l^2} \frac{I}{A} \left(1 + \frac{E}{kG}\right)}}$$

Effect of shearing force. The frequency equation and natural frequency of vibration are

$$\frac{n^2\pi^2}{l^2} \frac{m\omega^2}{kAG} + \frac{m\omega^2}{EI} = \frac{n^4\pi^4}{l^4}$$

$$\omega = \frac{n^2\pi^2}{l^2} \sqrt{\frac{EI}{m}} R$$

where the correction factor is

$$R = \frac{1}{\sqrt{1 + \frac{n^2\pi^2}{l^2} \frac{EI}{kAG}}}$$

Complete differential equation. Frequency equation and frequency of vibration

Effect of rotary motion and shearing force. The frequency equation, and natural frequency of vibration are

$$\begin{aligned} \frac{n^2\pi^2}{l^2} \frac{m\omega^2}{EA} \left(1 + \frac{E}{Gk}\right) + \frac{m\omega^2}{EI} \left(1 - \frac{mr_0^2}{AGk}\omega^2\right) &= \frac{n^4\pi^4}{l^4} \\ \omega_{1,2}^2 &= \frac{b_1 \pm \sqrt{b_1^2 - 4ac}}{2a} \end{aligned} \quad (11.18)$$

where

$$r_0^2 = \frac{I}{A}, \quad b_1 = \frac{m}{EI} + \frac{n^2\pi^2 m}{l^2 EA} \left(1 + \frac{E}{Gk}\right), \quad a = \frac{m^2 r_0^2}{EAGIk}, \quad c = \frac{n^4\pi^4}{l^4}$$

Effect of shearing force. The frequency equation, and natural frequency of vibration are

$$\begin{aligned} \frac{n^2\pi^2}{l^2} \frac{m\omega^2}{AGk} + \frac{m\omega^2}{EI} \left(1 - \frac{mr^2}{kAG}\omega^2\right) &= \frac{n^4\pi^4}{l^4} \\ \omega_{1,2}^2 &= \frac{b_2 \pm \sqrt{b_2^2 - 4ac}}{2a} \end{aligned}$$

where

$$b_2 = \frac{m}{EI} + \frac{n^2\pi^2 m}{l^2 AGk}$$

Effect of rotary motion. The frequency equation, and natural frequency of vibration are

$$\frac{n^2 \pi^2 m \omega^2}{l^2 EA} + \frac{m \omega^2}{EI} = \frac{n^4 \pi^4}{l^4}$$

$$\omega = \frac{n^2 \pi^2}{l^2} \sqrt{\frac{EI}{m}} \frac{1}{\sqrt{1 + r^2 \frac{n^2 \pi^2}{l^2}}}$$

Technical (Bernoulli–Euler) theory. The effects of rotary motion and shearing force are neglected.

The natural frequency of vibration is

$$\omega = \frac{n^2 \pi^2}{l^2} \sqrt{\frac{EI}{m}} \text{ (see Table 5.3)}$$

Different numerical approaches, vast numerical results and their detailed analysis are presented in Sekhniashvili (1960).

Approximate solution. The approximate expressions for the fundamental frequency of vibration of pinned–pinned beam are obtained by using the Bubnov–Galerkin method from the following assumptions (Sekhniashvili, 1960).

1. Elastic curve $y = \sin \pi x/l$, $E/kG \ll 1$

$$\omega_1 = \frac{\pi^2}{l^2} \sqrt{\frac{EI}{m}} R \quad R = \left[1 - \frac{1}{2} \pi^2 \frac{r_0^2}{l^2} \left(1 + \frac{E}{kG} \right) \right]$$

If correction factor $R < 0$ then one needs to use the following formula.

2. More precise formula; elastic curve $y = \sin \pi x/l$

$$\omega_1 = \frac{\pi^2}{l^2} \sqrt{\frac{EI}{m}} R$$

where the correction factor is

$$R = \sqrt{\frac{1}{1 + \pi^2 \frac{r_0^2}{l^2} \left(1 + \frac{E}{kG} \right)}}$$

3. The governing equation is a four-term differential one, the elastic curve neglects the effects of rotary motion and shearing force. Elastic curve

$$y = \frac{ml^4}{24EI} (\xi - 2\xi^3 + \xi^4), \quad \xi = \frac{x}{l}$$

In this case the fundamental frequency of vibration

$$\omega_1 = \frac{9.876}{l^2} \sqrt{\frac{EI}{m}} R$$

where the correction factor is

$$R = \sqrt{\frac{1}{1 + 9.871 \frac{r_0^2}{l^2} \left(1 + \frac{E}{kG}\right)}}$$

4. The elastic curve takes into account the effects of rotary motion and shearing force

$$y(x) = \frac{ml^4}{24EI} \left\{ \left[\frac{24(1+v)r_0^2}{kl^2} + 1 \right] \xi - 2\xi^3 + \xi^4 \right\}$$

where v is the Poisson coefficient.

Initial parameters are

$$y(0) = 0, \quad y'(0) = \frac{ml^3}{24EI} + \frac{ml}{2kGA}, \quad y''(0) = 0, \quad y'''(0) = -\frac{ml}{2}$$

The fundamental frequency of vibration

$$\begin{aligned} \omega_1 &= \frac{9.876}{l^2} \sqrt{\frac{EI}{m}} R, \quad R = \sqrt{\frac{A_0}{B_0}} \quad A_0 = 1 + 60 \frac{1}{k} (1+v) \frac{r_0^2}{l^2} \\ B_0 &= 1 + \frac{3654}{31} \frac{1}{k} (1+v) \frac{r_0^2}{l^2} + \frac{120960}{31} \frac{1}{k^2} (1+v)^2 \frac{r_0^2}{l^4} \\ &\quad + \frac{7560}{31} \frac{i^2}{l^2} \left[1 + 2 \frac{1}{k} (1+v) \right] \left[\frac{17}{420} + 2 \frac{1}{k} (1+v) \frac{r_0^2}{l^2} \right] \end{aligned}$$

5. Euler two-term differential equation; the elastic curve takes into account the effects of rotary motion and shearing force

$$y(x) = \frac{ml}{24EI} \left\{ \left[\frac{24(1+v)r_0^2}{kl^2} + 1 \right] \xi - 2\xi^3 + \xi^4 \right\}$$

The fundamental frequency of vibration

$$\begin{aligned} \omega_1 &= \frac{9.876}{l^2} \sqrt{\frac{EI}{m}} R, \quad R = \sqrt{\frac{A_0}{B_0}}; \quad A_0 = 1 + 60 \frac{1+v}{k} \cdot \frac{r_0^4}{l^2} \\ B_0 &= 1 + \frac{3654}{31} \frac{1+v}{k} \frac{r_0^2}{l^2} + \frac{120960}{31} \frac{(1+v)^2 r_0^2}{k^2 l^4} \end{aligned}$$

Correction factor R for pinned-pinned-beam, which are calculated using different governing equations and assumptions concerning elastic curves, are presented in Table 11.4.

11.3.2 Cantilever beam. Approximate solution

The frequency of the fundamental mode of vibration may be calculated by the formula

$$\omega_1 = \frac{3.529}{l^2} \sqrt{\frac{EI}{m}} R$$

TABLE 11.4. Pinned-pinned beam. Correction factor R for the fundamental mode of vibration including effects of rotary motion and shearing force. Beam with rectangular cross-section ($1/k = 3/2$, $1 + v = 1.25$)

Expr	h/l

(2)	0.9954	0.9811	0.9301	0.8603	0.7849	0.7114	0.6448	0.5860	0.5347	0.4902	0.4516	
(3)	0.9953	0.9810	0.9300	0.8601	0.7844	0.7112	0.6446	0.5858	0.5345	0.4900	0.4514	
(4)	0.9835	0.9411	0.8111	0.6776	0.5675	0.4808	0.4159	0.3647	0.3241	0.2912	0.2641	
(5)	0.9870	0.9562	0.8409	0.7333	0.6257	0.5376	0.4679	0.4124	0.3676	0.3310	0.3008	

1. Sign (–) means loss of physical meaning. In this case use expression (2).

2. Rows 1 and 2 have multiples $9.869/l^2(EI/m)^{1/2}$.

3. Rows 3,4,5 have multiples $9.876/l^2(EI/m)^{1/2}$.

where the correction factor is

$$R = \sqrt{\frac{A_1}{B_1}}, \quad A_1 = 1 + \frac{40}{3k}(1+v)\frac{r_0^2}{l^2}$$

$$B_1 = 1 + \frac{21.96}{k}(1+v)\frac{r_0^2}{l^2} + \frac{132.82}{k^2}(1+v)^2\frac{r_0^2}{l^4}$$

$$- \frac{135}{26}\frac{r_0^2}{l^2} \left[1 + \frac{2}{k}(1+v) \right] \left[\frac{1}{7} - \frac{1.6}{k}(1+v)\frac{r_0^2}{l^2} - \frac{64}{k^2}(1+v)^2\frac{r_0^4}{l^4} \right]$$

Galerkin's method has been applied; the expression for the elastic curve takes into account the shear effect (Sekhniashvili, 1960).

11.3.3 Clamped beam. Approximate solution

The frequency of the fundamental mode of vibration may be calculated by the formula

$$\omega_1 = \frac{22.449}{l^2} \sqrt{\frac{EI}{m}} R$$

where the correction factor

$$R = \sqrt{\frac{A_2}{B_2}}, \quad A_2 = 1 + \frac{120}{k}(1+v)\frac{r_0^2}{l^2}$$

$$B_2 = 1 + \frac{216}{k}(1+v)\frac{r_0^2}{l^2} + \frac{12096}{k^2}(1+v)^2\frac{r_0^4}{l^4}$$

$$+ 1260\frac{r_0^2}{l^2} \left[1 + \frac{2}{k}(1+v) \right] \left[\frac{71}{105} + \frac{1.6}{k}(1+v)\frac{r_0^2}{l^2} + \frac{96}{k^2}(1+v)^2\frac{r_0^4}{l^4} \right]$$

Galerkin's method has been applied; the expression for the elastic curve takes into account the shear effect.

Correction factor R for one-span beams with different values $h : l$ for prismatic beams or $r_0^2 : l^2$ for beams of any cross section are presented in Table 11.5. These data correspond to static elastic curves, which takes into account the effects of rotary motion and shear force.

TABLE 11.5. Correction factor R for prismatic beams with different boundary conditions and values $h : l$ or $r_0^2 : l^2$

$$\left(r_0^2 = \frac{l}{A}; k = 2/3, v = 0.25 \right)$$

11.4 BEAMS WITH A LUMPED MASS AT THE MIDSPAN

The frequency equations for one-span Timoshenko beams with different boundary conditions and one additional lumped mass are presented.

11.4.1 Simply supported beam

The design diagram is presented in Fig. 11.3(a).

Symmetric modes of vibration. The frequency equation may be written as follows

$$b^4 \beta \alpha (\beta^2 + \alpha^2) \cosh \frac{b\beta}{2} \cosh \frac{b\alpha}{2} + nb^2 \left[b\beta \left(d - \frac{s^2}{2} b^2 \beta^2 \right) \sinh \frac{b\alpha}{2} \cos \frac{b\beta}{2} - b\alpha \left(d - \frac{s^2}{2} b^2 \alpha^2 \right) \right] \sin \frac{b\beta}{2} \cosh \frac{b\alpha}{2} = 0 \quad (11.19)$$

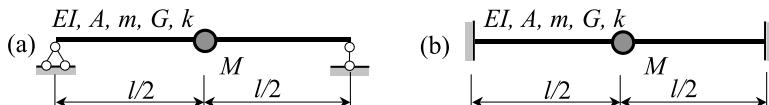

FIGURE 11.3 Uniform one-span beams with lumped mass in the middle of the span.

where

$$\begin{aligned} \begin{pmatrix} b\alpha \\ b\beta \end{pmatrix} &= \frac{b}{\sqrt{2}} \sqrt{\mp(r^2 + s^2) + \sqrt{(r^2 - s^2)^2 + \frac{4}{b^2}}} \\ b^2 &= \frac{ml^4}{EI}\omega^2, \quad r^2 = \frac{l}{Al^2} = \frac{r_0^2}{l^2}, \quad s^2 = \frac{EI}{kAl^2G} = r^2 \frac{E}{kG} \\ d &= \frac{1}{2} \left[1 + b^2 r^4 \left(\frac{E}{kG} \right)^2 \right] = \frac{1}{2}(1 + b^2 s^2), \quad n = \frac{M}{ml}, \quad r_0 = \sqrt{\frac{I}{A}} \end{aligned}$$

Here, r_0 is the radius of gyration of a cross-section, and r is the non-dimensional radius of gyration, which is the reciprocal of slenderness.

The frequency parameters b for the fundamental mode and different values $n = M/ml$ are presented in Table 11.6. Assume that $l/r_0 = r^{-1} = 20$, i.e. for rectangular cross-section $h : l \approx 1 : 5.8$; $k = 5/6$; $E/G = 23.33$ (Filippov, 1970).

TABLE 11.6. Simply supported uniform beam with lumped mass at the middle of the span: Fundamental frequency parameter according to two theories

	$n = M/ml$			
Frequency parameter b	0.045	0.638	2.270	4.370
Timoshenko's theory	9.00	6.25	4.00	3.00
Technical theory (b_0)	9.45	6.50	4.16	3.12
$(b_0 - b)100\% / b_0$	4.8	4.13	4.0	3.8

Vast numerical results for simply-supported beams with lumped mass along the span are presented in Maurizi and Belles (1991).

Antisymmetric modes of vibration. The frequency equation may be written as

$$\sin \frac{b\beta}{2} \sinh \frac{b\alpha}{2} = 0 \quad (11.20)$$

Special case: For Bernoulli-Euler theory, parameters $s = r = 0$, $\alpha = \beta = \frac{1}{\sqrt{b}}$. The frequency equation is $\sin \frac{\sqrt{b}}{2} = 0$ and frequency of vibration $\omega = \frac{4\pi^2}{l^2} \sqrt{\frac{EI}{M}}$.

11.4.2 Clamped beam

The design diagram is presented in Fig. 11.3(b).

Symmetric modes of vibration. The frequency equation may be written as follows (Filippov, 1970)

$$\begin{aligned} b^2(\beta^2 + \alpha^2) & \left(b\beta \cosh \frac{b\alpha}{2} \sin \frac{b\beta}{2} + b\alpha \sinh \frac{b\alpha}{2} \cos \frac{b\beta}{2} \right) \\ & + nb^2 \left\{ \left(\cos \frac{b\beta}{2} \cosh \frac{b\alpha}{2} - 1 \right) \left[2d - b^2 \frac{s^2}{2} (\beta^2 - \alpha^2) \right] \right. \\ & \left. - \frac{1}{\beta\alpha} \sinh \frac{b\alpha}{2} \sin \frac{b\beta}{2} \left[\frac{b^2 s^2}{2} (\beta^4 + \alpha^4) - d(\beta^2 - \alpha^2) \right] \right\} = 0 \quad (11.21) \end{aligned}$$

The frequency parameters b for the fundamental mode and different values $n = M/ml$ are presented in Table 11.7. Assume that $l/r_0 = 20$, i.e. for rectangular cross-section $h : l \approx 1 : 5.8$; $k = 5/6$; $E/G = 23.33$ (Filippov, 1970).

TABLE 11.7. Clamped uniform beam with lumped mass at the middle of the span: Fundamental frequency parameter according to two theories

	$n = M/ml$			
Frequency parameter b	0.053	0.319	0.851	1.78
b (Timoshenko's theory)	20	16	12	9
b_0 (Technical theory)	21.1	16.78	12.58	9.43
$(b_0 - b)100\% / b_0$	5.22	4.65	4.60	4.55

Antisymmetric modes of vibration. The frequency equation may be written as

$$\frac{1}{\beta} \sin \frac{b\beta}{2} \cosh \frac{b\alpha}{2} - \frac{1}{\alpha} \sinh \frac{b\alpha}{2} \cos \frac{b\beta}{2} = 0 \quad (11.22)$$

11.5 CANTILEVER TIMOSHENKO BEAM OF UNIFORM CROSS-SECTION WITH TIP MASS AT THE FREE END

The frequency coefficients for the first five modes of vibration of the Timoshenko beam of uniform cross-section are presented in Table 11.8 (Rossi *et al.*, 1990).

Notation

$$\Omega^2 = \rho AL^4 \omega^2/EI; \quad n = M/ml; \quad r^2 = I/AL^2; \quad v = 0.3; \quad k = 5/6.$$

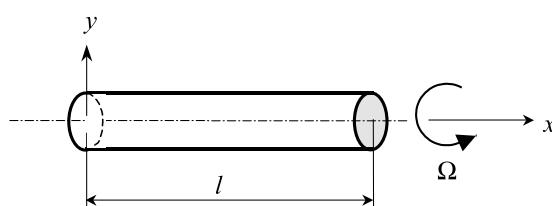

11.6 UNIFORM SPINNING BRESS-TIMOSHENKO BEAMS

In this section, a free vibration analysis of a spinning, finite Timoshenko beam with general boundary conditions is presented. Analytical solutions of the frequency equations and mode shapes are given for six types of boundary conditions.

TABLE 11.8 Timoshenko cantilever uniform beam with tip mass at the free end: Frequency parameters for different mode shapes

	1.0	1.47	11.59	27.62	45.19	59.82

The case of $n = 10^7$ corresponds, from a practical engineering viewpoint, to the Bernoulli–Euler theory.

**FIGURE 11.4** Spinning Bress-Timoshenko beam (boundary conditions are not shown).

11.6.1 Fundamental equations

A spinning beam and its frame of reference are presented in Fig. 11. 4.

Differential equations The transverse deflections along $0z$, $0y$ axis are represented by $u_y, u_z, y = u_z + j u_y$; and their corresponding bending angles by ψ_y, φ_z , so $\phi = \varphi_z + j \psi_y$. Differential equation may be presented as follows (Zu and Han, 1992).

$$\begin{aligned} EI \frac{\partial^4 y}{\partial \xi^4} + \rho A \frac{\partial^2 y}{\partial t^2} - \frac{\rho I}{l^2} \left(1 + \frac{E}{kG}\right) \frac{\partial^4 y}{\partial \xi^2 \partial t^2} + \frac{\rho^2 I}{kG} \frac{\partial^4 y}{\partial t^4} - j\Omega \frac{\rho J}{kG} \frac{\partial^3 y}{\partial t^3} + j \frac{\Omega J}{l^2} \frac{\partial^3 y}{\partial \xi^2 \partial t} &= 0 \\ EI \frac{\partial^4 \psi}{\partial \xi^4} + \rho A \frac{\partial^2 \psi}{\partial t^2} - \frac{\rho I}{l^2} \left(1 + \frac{E}{kG}\right) \frac{\partial^4 \psi}{\partial \xi^2 \partial t^2} + \frac{\rho^2 I}{kG} \frac{\partial^4 \psi}{\partial t^4} - j\Omega \frac{\rho J}{kG} \frac{\partial^3 \psi}{\partial t^3} + j \frac{\Omega J}{l^2} \frac{\partial^3 \psi}{\partial \xi^2 \partial t} &= 0 \end{aligned} \quad (11.23)$$

where x is the spatial coordinate along the beam axis, $\xi = x/l$; y and ψ are the total deflection and bending slope; E , G , ρ and k are Young's modulus, shear modulus, mass density and shear coefficient; A , l are the cross-sectional area and length of beam; I and J are the transverse moment of inertia of an axisymmetric cross-section and the polar mass moment of inertia, respectively; Ω is rotational speed; $j^2 = -1$.

Solution

$$\begin{aligned} y &= X(\xi)T(t) = X_0 \exp(jp\xi) \exp(j\omega t) \\ \psi &= \Psi(\xi)T(t) = \Psi_0 \exp(j\psi) \exp(j\omega t) \end{aligned}$$

where X_0 and Ψ_0 are complex amplitudes, ω is the natural frequency and p is the coefficient characterizing the normal modes.

Characteristic equation

$$p^4 - \frac{B}{A}p^2 + \frac{C}{A} = 0 \quad (11.24)$$

where

$$\begin{aligned} A &= \frac{EI}{\rho Al^2} \\ B &= \frac{I}{Al^2} \left(1 + \frac{E}{kG}\right) \omega^2 - \frac{\Omega J}{\rho Al^2} \omega \\ C &= \frac{\rho I}{kAG} \omega^4 - \frac{\Omega J}{kAG} \omega^3 - \omega^2 \end{aligned}$$

The roots of the characteristic equation are $p_1 = \pm js_1, p_2 = \pm s_2$, where

$$\begin{pmatrix} s_1 \\ s_2 \end{pmatrix} = \sqrt{\frac{\mp B + \sqrt{B^2 - 4AC}}{2A}} = \frac{1}{\sqrt{2}} \sqrt{\mp \frac{B}{A} + \sqrt{\frac{B^2}{A^2} - \frac{4C}{A}}}$$

The roots of the equation in terms of $b^2 = \frac{ml^4}{EI} \omega^2, r^2 = \frac{I}{Al^2}, s^2 = r^2 \frac{E}{kG}$ and $f = \frac{J\omega^2}{kAG}$ are

$$\begin{pmatrix} s_1 \\ s_2 \end{pmatrix} = \frac{b}{\sqrt{2}} \sqrt{\mp \left[(r^2 + s^2) - 2 \frac{\Omega}{\omega} r^2 \right] + \sqrt{(r^2 - s^2)^2 - 4(r^2 + s^2) \frac{\Omega}{\omega} r^2 + 4 \frac{\Omega^2}{\omega^2} r^4 + \frac{4}{b^2} \left(\frac{\Omega}{\omega} f + 1 \right)}}$$

Clamped-clamped	$c'_1 (\cos s'_1 - \cos s_2)^2 + (c'_1 \sin s'_1 - c_2 \sin s_2) \left(\sin s'_1 - \frac{c'_1}{c_2} \sin s_2 \right) = 0$	$X = D \left(\cos s'_1 \xi + \frac{d'}{c'_1} \sin s'_1 \xi - d' \cos s'_1 \xi - d' \cos s'_1 \xi - c_2 \sin s_2 \xi + d' \sin s_2 \xi \right)$ $\psi = H(c'_1 \sin s'_1 \xi - d' \cos s'_1 \xi - c_2 \sin s_2 \xi - \frac{d'}{c_2} \sin s_2 \xi)$	$d' = \frac{c'_1 \sin s'_1 - c'_2 \sin s_2}{\cos s'_1 - \cos s_2}$
Clamped-free	$(c'_1 s'_1 \cos s'_1 - c_2 s_2 \cos s_2) \times \left[\left(\frac{s'_1}{l} + c'_1 \right) \cos s'_1 - \frac{c'_1}{c_2} \left(\frac{s_2}{l} + c_2 \right) \cos s_2 \right] + c'_1 (s'_1 \sin s'_1 - s_2 \sin s_2) \times \left[\left(\frac{s'_1}{l} + c'_1 \right) \sin s'_1 - \left(\frac{s_2}{l} + c_2 \right) \sin s_2 \right] = 0$	$X = D \left(\cos s'_1 \xi - \frac{d'}{c'_1} \sin s'_1 \xi - \cos s_2 \xi + \frac{d'}{c_2} \sin s_2 \xi \right)$ $\psi = H(c'_1 \sin s'_1 \xi + d' \cos s'_1 \xi - c_2 \sin s_2 \xi - d' \cos s_2 \xi)$	$d' = \frac{c'_1 s'_1 \cos s'_1 - c_2 s_2 \cos s_2}{s'_1 \sin s'_1 - s_2 \sin s_2}$
Clamped-pinned	$c'_1 (\cosh s'_1 - \cos s_2) (s'_1 \sinh s'_1 + s_2 \sin s_2) - \left(\sinh s'_1 + \frac{c'_1}{c_2} \sin s_2 \right) \times (c'_1 s'_1 \cosh s'_1 - c_2 s_2 \cos s_2) = 0$	$X = D \left(\cosh s'_1 \xi - \frac{d'}{c'_1} \sinh s'_1 \xi - \cos s_2 \xi - \frac{d'}{c_2} \sinh s'_1 \xi \right)$ $\psi = H(c'_1 \sinh s'_1 \xi + d' \cosh s'_1 \xi - c_2 \sinh s'_1 \xi + d' \cos s_2 \xi)$	$d' = \frac{c'_1 \cosh s'_1 \cos s'_1 - c_2 \sinh s'_1 \cos s_2}{\sinh s'_1 \xi - \frac{d'}{c_2} \sin s_2 \xi}$
Hinged-free	$c'_1 s'_1 \left(\frac{s'_2}{l} + c'_2 \right) \sinh s'_1 \cos s_2 - c_2 s_2 \left(\frac{s'_1}{l} + c'_1 \right) \cosh s'_1 \sin s_2 = 0$	$X = D \left(\sinh s'_1 \xi - \frac{d'}{c_2} \sin s_2 \xi \right)$ $\psi = H(c'_1 \cosh s'_1 \xi + d' \cos s_2 \xi - c_2 \sinh s'_1 \xi + d' \cos s_2 \xi)$	$d' = \frac{c'_1 s'_1 \sin s'_1}{s_2 \sin s_2}$

If $\Omega = 0$, then the equation for $s_{1,2}$ reduces to the following formula (Section 11.3.1)

$$\left(\begin{array}{c} bx \\ b\beta \end{array} \right) = \frac{b}{\sqrt{2}} \sqrt{\mp(r^2 + s^2) + \sqrt{(r^2 - s^2)^2 + \frac{4}{b^2}}}$$

It is necessary to differentiate between two cases.

Case 1

$$\sqrt{B^2 - 4AC} > B \quad \text{or} \quad C < 0$$

In this case the roots are $p_{1,2} = \pm js_1, \pm s_2$. This case would correspond to lower frequencies of vibrations.

Case 2

$$\sqrt{B^2 - 4AC} < B \quad \text{or} \quad C > 0$$

In this case, the roots are $p_1 = \pm s'_1$ in which $s'_1 = js_2$. This case would correspond to higher frequencies of vibrations.

The frequency equation and mode shape of vibration are presented in Tables 11.9 and 11.10 for cases 1 and 2, respectively. Additional parameters are

$$c_1 = \frac{1}{s_1} \left(\frac{\rho l}{kG} \omega^2 + \frac{s_1^2}{l} \right) \quad c_2 = \frac{1}{s_2} \left(\frac{\rho l}{kG} \omega^2 - \frac{s_2^2}{l} \right) \quad c'_1 = \frac{1}{s'_1} \left(\frac{\rho l}{kG} \omega^2 - \frac{s'_1^2}{l} \right)$$

Numerical results have been obtained, analysed and discussed by Zu and Han, (1992).

CHAPTER 12

NON-UNIFORM ONE-SPAN BEAMS

In this chapter, free vibration analyses of non-uniform one-span beams with different boundary conditions are presented. Continuous and stepped beams are investigated.

NOTATION

A	Cross-sectional area of the beam
E	Modulus of elasticity of the beam material
EI	Bending stiffness
h, d, b	Geometrical dimensions of the cross-sectional of the beam
I	Moment of inertia of a cross-sectional area of the beam
k	Stiffness coefficient of a transversal spring
k_F	Stiffness coefficient of the elastic foundation
l	Length of the beam
t	Time
x	Spatial coordinate
x, y, z	Cartesian coordinates
$X(x)$	Mode shape
$y(x, t)$	Lateral displacement of the beam
α	Taper parameter
λ	Frequency parameter
ρ, m	Density of material and mass per unit length of beam, $m = \rho A$
ϕ	Flexibility constant of the rotational spring
ω	Circular natural frequency of the transverse vibration of the beam

12.1 CANTILEVER BEAMS

12.1.1 Wedge and truncated wedge

A wedge and truncated wedge of length l are presented in Figs. 12.1(a) and (b).

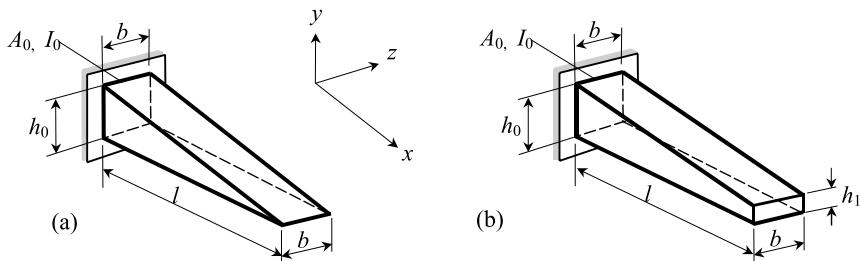

FIGURE 12.1. Tapered cantilever beam: (a) wedge; (b) truncated wedge.

The differential equation for the Bernoulli–Euler theory

$$\rho A(x) \frac{\partial^2 y(x, t)}{\partial t^2} = - \frac{\partial^2}{\partial x^2} \left[EA(x) r^2(x) \frac{\partial^2 y(x, t)}{\partial x^2} \right] \quad (12.1)$$

where $r(x)$ is the radius of gyration of a cross-section about an axis through its centre parallel to the z axis.

Wedge. The natural frequency of vibration is

$$\omega = \frac{\lambda}{l^2} \sqrt{\frac{EI_0}{\rho A_0}} \quad (12.2)$$

where A_0 = cross-sectional area in the root section

I_0 = second moment of inertia in the root section

λ = frequency parameter.

Bernoulli–Euler theory. Exact values of λ for the three lowest frequencies of vibrations are 5.315, 15.202 and 30.019, respectively.

Timoshenko theory. Approximate values of the frequency parameters, λ , in terms of the geometrical parameter, $\alpha = l/h_0$, are presented in Table 12.1, $E/G = 2.6$, shear coefficient $k = 0.833$ (bars of rectangular cross-section). The Rayleigh–Ritz method is applied (Gaines and Volterra, 1966).

Truncated wedge. The dimensionless frequency parameter λ , and the geometrical coefficients χ and α relating to vibration in the vertical plane are (Fig. 12.1(b))

$$\lambda^2 = \frac{\rho A_0 \omega^2 l^4}{EI_0}, \quad \chi = \frac{h_1}{h_0}$$

The frequency parameters according to the Bernoulli–Euler and Timoshenko theories are presented.

Bernoulli–Euler theory. Approximate values for the upper and lower bound of the frequency parameters λ for different χ are presented in Table 12.2 (Gaines and Volterra, 1966).

Timoshenko theory. The approximate values for the upper and lower bounds of the frequency parameters λ for $\chi = h_1/h_0 = 0.5$ and different parameters $\alpha = l/h_0$ are presented in Table 12.3; $E/G = 2.6$; $k = 0.833$ for bars of rectangular cross-section.

12.1.2 Cone and truncated cone

The clamped-free cone and truncated cone of length l are presented in Figs. 12.2(a) and (b).

Cone. The natural frequency of vibration is

$$\omega = \frac{\lambda}{l^2} \sqrt{\frac{EI_0}{\rho A_0}}$$

where A_0 = cross-sectional area in the root section

I_0 = second moment of inertia in the root section

λ = frequency parameter.

Bernoulli–Euler theory. Exact values of λ of the three lowest frequency parameters of vibrations are 8.719 (see Table 12.5), 21.146 and 38.453, respectively (Volterra and Zachmanoglou, 1965).

Timoshenko theory. Approximate values of frequency parameters λ in terms of geometrical parameter $\alpha = l/d_0$ are presented in Table 12.4. The Rayleigh–Ritz method is applied; $E/G = 2.6$; $k = 0.9$ (Gaines and Volterra, 1966).

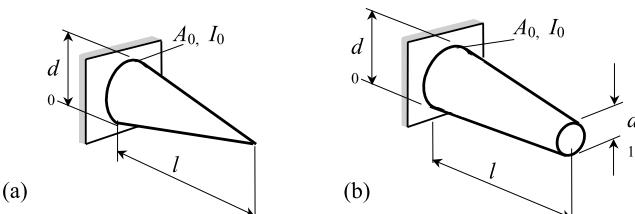

FIGURE 12.2. Tapered cantilever beam: (a) cone; (b) truncated cone.

∞	8.7193	8.6628	21.1457	20.3766	38.4540	34.3348

Truncated cone.

Bernoulli–Euler theory. *Analytical expression.* The fundamental frequency of vibration may be calculated by the formula (Dunkerley–Mikhlin estimates) (Brock, 1976)

$$\omega_1 \cong 8.72 \sqrt{\frac{1 - 0.016\delta}{1 + 5.053\delta} \frac{EI_0}{m_0 l^4}}, \quad m_0 = \pi \frac{d_0^2}{4} \rho, \quad \delta = \frac{d_1}{d_0} \quad (12.3)$$

where ρ is mass density. There is a maximum error of 1.4% for $\delta = 0.1$. The exact results, for comparison, were calculated from formulas given by Conway *et al.* (1964).

Numerical results. For the beam presented in Fig. 12.2(b), the approximate upper and bound values of the frequency parameters λ are presented in Table 12.5. The Rayleigh–Ritz method has been applied (Gaines and Volterra, 1966).

Natural frequency of vibration is

$$\omega = \frac{\lambda}{l^2} \sqrt{\frac{EI_0}{\rho A_0}}$$

where A_0 = cross-sectional area in the root section

I_0 = second moment of inertia in the root section

λ = frequency parameter.

* Table 14.3 presents fundamental parameters for the case $\varepsilon = 1 - \delta$.

† Parameter λ is presented in Table 5.3, case 4; this case corresponds to a uniform cantilever beam.

The above-mentioned reference present frequency parameters λ for truncated-cone beams with different boundary conditions.

Timoshenko theory. The natural frequency of vibration is

$$\omega = \frac{\lambda}{l^2} \sqrt{\frac{EI_0}{\rho A_0}}$$

where A_0 = cross-sectional area in the root section

I_0 = second moment of inertia in the root section

λ = frequency parameter.

Approximate results for upper and lower values of the three lowest frequency parameters λ for $\delta = \frac{d_1}{d_0} = 0.5$ and different parameters α are presented in Table 12.6; $E/G = 2.6$, $k = 0.9$ for bars of circular cross-section (Gaines and Volterra, 1966).

12.1.3 Doubly tapered beam

A doubly tapered clamped-free beam is presented in Fig. 12.3.

The dimensionless tapered parameters are

$$D = \frac{d_1}{d_0}, \quad H = \frac{h_1}{h_0}$$

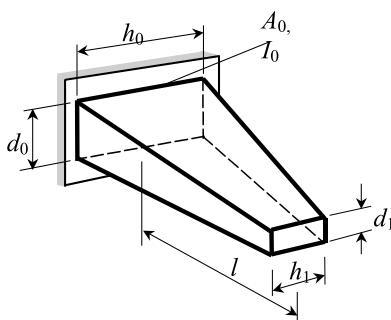

FIGURE 12.3. Doubly-tapered cantilever beam.

The natural frequency of vibration is

$$\omega = \frac{\lambda}{l^2} \sqrt{\frac{EI_0}{\rho A_0}}$$

where A_0 = cross-sectional area in the root section

I_0 = second moment of inertia in the root section

λ = frequency parameter

Frequency parameters, λ , for both Bernoulli–Euler and Timoshenko models of beams are presented in Table 12.7 (Downs, 1977). The results obtained by using the Bernoulli–Euler theory (identified by the letter E) can be applied to any material and slenderness ratio, but for the results based on Timoshenko theory (identified by the letter T), Poisson's ratio $\nu = 0.3$, the ratio of the radius of gyration at the cantilever root to beam length equals 0.08, and the shear coefficient of 0.85 applies.

*Special cases:** $D = 0, H = 1$. This case corresponds to a clamped-free wedge (Table 12.1).** $D = 1, H = 1$. This case corresponds to a cantilever uniform beam (Table 5.3).

12.1.4 Tapered beams with a tip mass

Bernoulli-Euler theory. Tapered beams with a tip mass at the free end ($x = L_0$) and clamped at $x = L_1 = L + L_0$ are presented in Fig. 12.4.

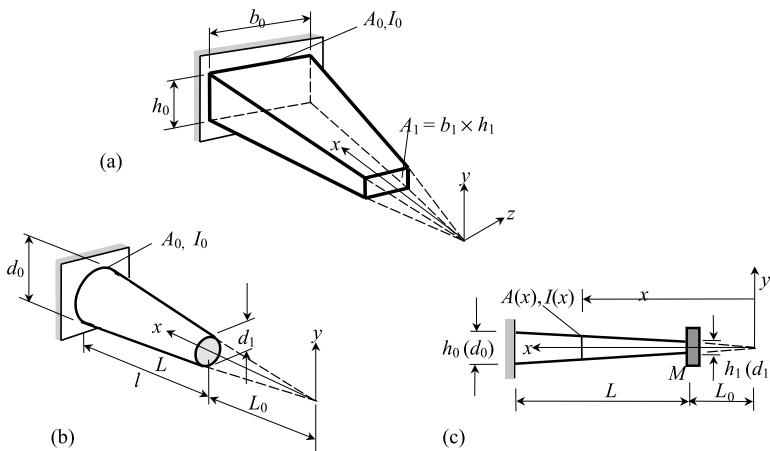

FIGURE 12.4. (a) Truncated pyramid; (b) truncated cone; (c) general notation for a pyramid and cone with a tip mass.

The flexural rigidity, $EI(x)$, and the area of cross-section, $A(x)$, are given by

$$EI(x) = \left(\frac{x}{L_1}\right)^4 EI_0 \quad (12.4)$$

$$A(x) = \left(\frac{x}{L_1}\right)^2 A_0 \quad (12.5)$$

where A_0 = the cross-section area at $x = L_1$ (root section)

I_0 = second moment of inertia at $x = L_1$.

Formulas (12.4) and (12.5) may be applied to doubly truncated pyramids (Fig. 12.4(a)) and truncated cones (Fig. 12.4(b),(c)).

The differential equation for mode shape X is

$$\frac{1}{y_*^2} \frac{d^2}{dy_*^2} \left(y_*^4 \frac{d^2X}{dy_*^2} \right) - \lambda^4 X = 0, \quad y_* = \frac{x}{L_1} \quad (12.6)$$

The general solution may be written by using Bessel functions

$$X = y_*^{-1} [C_1 J_2(z) + C_2 Y_2(z) + C_3 I_2(z) + C_4 K_2(z)], \quad z = 2\lambda\sqrt{y_*} \quad (12.7)$$

where J_2 and Y_2 are the second-order Bessel functions of the first and second kind, respectively; I_2 and K_2 are the modified second-order Bessel functions of the first and second kind, respectively.

The frequency equation is presented by Lau (1984).

The natural frequency of vibration is

$$\omega = \frac{\lambda^2}{L^2} \sqrt{\frac{EI_0}{\rho A_0}} \quad (12.8)$$

Frequency coefficients, λ , for different modes of vibration in terms of dimensionless mass ratio $\eta = \frac{M}{\rho A_0 L}$ and geometry ratio $\frac{L_0}{L_1}$ are presented in Table 12.8 (Lau, 1984).

In this table Parameter $L_0/L_1 = 1$ corresponds to a uniform beam (Table 5.3). Case * corresponds to a uniform beam without lumped mass. Case ** corresponds to a uniform beam with lumped mass.

Timoshenko theory. A cantilevered tapered beam with a tip mass at the free end is presented in Fig. 12.5. The width of the cross-section is assumed to be constant.

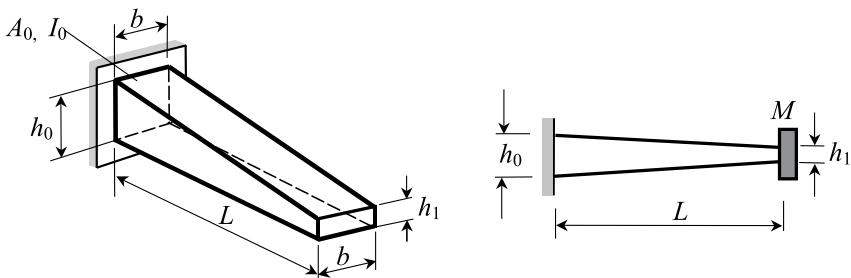

FIGURE 12.5. Cantilever tapered beam with end mass.

The governing equations and frequency equation are presented by Rossi *et al.* (1990). The natural frequency of vibration is

$$\omega = \frac{\lambda^2}{L^2} \sqrt{\frac{EI_0}{\rho A_0}}$$

where A_0 = cross-sectional area in the root section

I_0 = second moment of inertia in the root section

λ = frequency parameter.

Table 12.9 shows the first four frequency coefficients λ for different combinations of the geometry ratio h_1/h_0 , dimensionless parameters $\eta = I_0/(A_0 L)^2$ and mass ratio $\mu = M/M_b$ (M_b is total beam mass). The finite element method has been applied for Poisson's coefficient $\nu = 0.3$, and shear coefficient $k = 5/6$ (Rossi *et al.*, 1990).

12.1.5 Haunched beam with a tip mass at the free end

A haunched beam with a tip mass at the free end is shown in Fig. 12.6. The width of the cross-section is assumed to be constant.

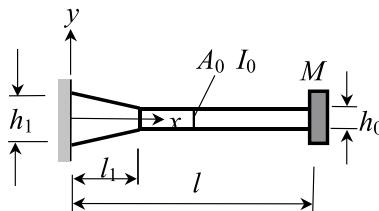

FIGURE 12.6. Cantilevered haunched beam.

In the range from $x = 0$ (clamped end) to $x = l_1$ the area and moment of inertia are

$$A(x) = A_0 \left[1 + k \left(1 - \frac{x}{l_1} \right) \right] \quad (12.9)$$

$$I(x) = I_0 \left[1 + k \left(1 - \frac{x}{l_1} \right) \right]^3 \quad (12.10)$$

where the dimensionless parameters are

$$k = \frac{2a}{h_0}, \quad a = \frac{h_1 - h_0}{2}$$

The natural fundamental frequency of vibration, according to the Bernoulli–Euler theory, may be calculated by

$$\omega = \frac{357}{l_r^2} \sqrt{\frac{EI_0}{\left(1 + \frac{140}{35} \frac{M}{\rho A_0 l} \right) \rho A_0}} \quad (12.11)$$

where the reduced length of the beam is $l_r = \phi l$; A_0 and I_0 are the cross-sectional area and moment of inertia of any cross-section at $l_1 \leq x \leq l$.

Parameter ϕ is presented in Table 12.10 in terms of geometry ratios $n = h_1/h_0$ and $\eta = l_1/l$. The Rayleigh–Ritz method has been applied. If η and k are small, then the kinetic energy of the haunched part of the beam is neglected (Filippov, 1970).

TABLE 12.10 Parameter ϕ for a reduced length of a cantilever haunched beam

$\eta = \frac{l_1}{l}$	Parameter $n = h_1/h_0$

Expression for mode shape of vibration is

$$a_1 X(x) = a_1 \frac{x^2(3l-x)}{2l^3} \quad (12.12)$$

12.2 STEPPED BEAMS

12.2.1 Bernoulli–Euler beams with different boundary conditions

A beam with a discontinuous variation of thickness is presented in Fig. 12.7.

The natural frequency of vibrations is

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI_1}{\rho A_1}}, \quad l = l_1 + l_2$$

The exact frequency equations for beams with different boundary conditions are presented in Table 12.11. The dimensionless frequency and geometry parameters are

$$k = \frac{k_2}{k_1}, \quad k_i^4 = \frac{\rho A_i}{EI_i} \omega^2, \quad i = 1, 2 \quad \text{and} \quad I = \frac{I_2}{I_1}$$

Notation:

$$\begin{aligned} S1 &= \sin k_1 l_1, & S2 &= \sin k_2 l_2, & C1 &= \cos k_1 l_1, & C2 &= \cos k_2 l_2, \\ SH1 &= \sinh k_1 l_1, & SH2 &= \sinh k_2 l_2, & CH1 &= \cosh k_1 l_1, & CH2 &= \cosh k_2 l_2. \end{aligned}$$

FIGURE 12.7. Stepped-beam geometry. The types of supports are not shown.

Special case:
 * Frequency parameters for uniform beams (Table 5.3).

Table 12.11 also shows the exact solution, λ^2 , of the fundamental mode of vibration for beams with circular cross-section with $l_1 = l_2 = l/2$, $A_2 = \alpha A_1$, $I = I_2/I_1 = \alpha^2$ (Jano and Bert, 1989).

12.2.2 Stepped-cantilever Bernoulli–Euler beam

A stepped clamped–free beam is presented in Fig. 12.8.

Natural frequencies of vibration may be calculated by the formula

$$\omega_i = \frac{\lambda_i}{l^2} \sqrt{\frac{EI_1}{m_1}} \quad (12.12)$$

The frequency parameters λ_i are presented in Table 12.12 for the dimensionless geometry ratio $H = \frac{h_2}{h_1}$, mass ratio $\frac{m_2}{m_1} = H^2$; $\frac{EI_2}{EI_1} = H^4$ for $H = 0.2$.

Finite element method higher degree polynomials have been used (Balasubramanian *et al.*, 1990).

The finite element method has been applied ([Laura *et al.*, 1989; Bambill and Laura, 1989]).

12.2.4 Cantilever Timoshenko beam with tip mass

Details of a stepped clamped-free beam having constant width b and a mass M at the tip are shown in Fig. 12.10.

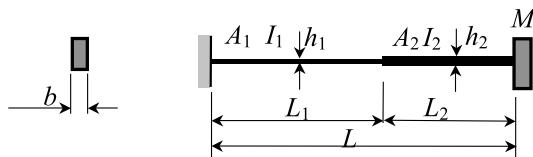

FIGURE 12.10. Clamped-free beam with concentrated mass M .

Dimensionless parameters are

$$\gamma_A = \frac{A_2}{A_1}, \quad \gamma_L = \frac{L_1}{L}, \quad \eta = \frac{I_1}{A_1 L_1^2}, \quad \mu = \frac{M}{M_b}$$

where M_b is the total beam mass.

Natural frequencies of vibration may be calculated by

$$\omega = \frac{\lambda}{L^2} \sqrt{\frac{EI_1}{\rho A_1}}$$

The frequency parameters, λ , for beams with shear factor $k = 5/6$, Poisson ratio $\nu = 0.3$ and different combinations of the parameters η , γ_L , γ_A and μ are listed in Table 12.14 (Rossi *et al.*, 1990). The case of $\eta = 10^{-7}$ corresponds, from a practical engineering viewpoint, to the classical Bernoulli–Euler theory of vibrating beams.

12.3 ELASTICALLY RESTRAINED BEAMS

12.3.1 Tapered Bernoulli–Euler beam with one end spring-hinged and a tip body at the free end

Consider a rectangular beam of depth h , tapered linearly in the vertical plane and of constant width b in the horizontal plane (Fig. 12.11). The rotational spring constant is k ; a body attached at the free end has a mass M and a rotatory inertia J .

The tapered parameter of the beam is $\alpha = (h_0 - h_1)/h_0$. The cross sectional area, flexural rigidity and the total beam mass M_b are given by

$$A(x) = A_0 \left(1 - \alpha \frac{x}{l}\right), \quad A_0 = bh_0 \quad (12.13)$$

$$EI(x) = EI_0 \left(1 - \alpha \frac{x}{l}\right)^3, \quad I_0 = \frac{bh_0^3}{12} \quad (12.14)$$

$$M_b = \rho A_0 l \left(1 - \frac{\alpha}{2}\right) \quad (12.15)$$

The differential equation for eigenfunctions X is given by

$$\frac{d^2}{d\xi^2} \left(\xi^3 \frac{d^2 X}{d\xi^2} \right) - \beta^4 \xi X = 0 \quad (12.16)$$

where $\xi = 1 - \alpha \frac{x}{l}$. Frequency parameter

$$\beta^4 = \frac{\rho A_0}{EI_0} \omega^2 \frac{l^4}{\alpha^4} = \frac{\lambda^4}{\alpha^4} \quad (12.17)$$

The boundary conditions are:

$$\text{At } \xi = 1 \text{ (left end):} \quad y = 0 \quad \text{and} \quad \frac{kl}{EI_0} \frac{dX}{d\xi} + \alpha \frac{d^2X}{d\xi^2} = 0 \quad (12.18)$$

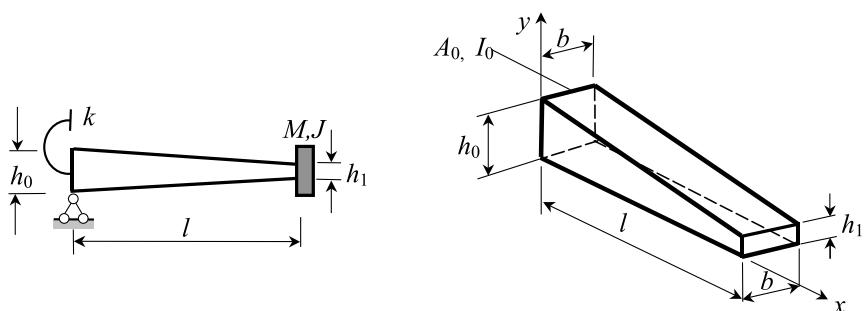

FIGURE 12.11. Elastic-clamped tapered beam with a body attached at the free end.

At $\xi = 1 - \alpha$ (right end):

$$\begin{aligned} \frac{J}{M_b l^2} \lambda_n^4 \left(1 - \frac{\alpha}{2}\right) \frac{dX}{d\xi} + \alpha(1-\alpha)^3 \frac{d^2 X}{d\xi^2} &= 0 \\ \frac{M}{M_b} \lambda_n^4 \left(1 - \frac{\alpha}{2}\right) X - \alpha^3(1-\alpha)^2 \left[3 \frac{d^2 X}{d\xi^2} + (1-\alpha) \frac{d^3 X}{d\xi^3} \right] &= 0 \end{aligned} \quad (12.19)$$

The general expression for the vibration mode is expressed as

$$X(\xi) = \xi^{-1/2} [C_1 J_1(Z) + C_2 Y_1(Z) + C_3 I_1(Z) + C_4 K_1(Z)], \quad Z = 2\beta\sqrt{\xi} \quad (12.20)$$

where J , Y , I and K are Bessel functions of the first order with argument Z .

The frequency equation can be obtained by using the expression for $X(\xi)$ and the boundary conditions. The complete frequency equation is presented by Lee (1976).

The natural frequency of vibration of the i th mode is

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI_0}{\rho A_0}}$$

The frequency parameters λ for various values of the spring stiffness, end mass, rotary inertia and taper parameter are shown in Table 12.15 (Lee, 1976).

Elastic-clamped tapered Bernoulli-Euler beams with a tip body at the free end and with translational and rotational springs along the space are studied by Yang (1990).

12.3.2 Tapered simply supported Timoshenko beam with ends elastically restrained against rotation

A simply supported non-uniform beam with two rotational springs is presented in Fig. 12.12. The thickness b of the beam is constant and the depth is tapered linearly in the plane of vibration. The parameters h , A and I are the depth, cross-sectional area and the moment of inertia; subscripts 0 and 1 denote the values at the left and right-hand supports, respectively; ϕ_1 and ϕ_2 are the flexibility constants of the rotational springs.

The cross-sectional area and flexural rigidity are given by

$$A(x) = A_0 \left(1 + \frac{\alpha x}{L}\right) \quad (12.31)$$

$$EI(x) = EI_0 \left(1 + \frac{\alpha x}{L}\right)^3 \quad (12.32)$$

The taper parameter and the dimensionless parameters of the beam are

$$\alpha = \frac{h_1 - h_0}{h_0} \geq 0, \quad \eta_0 = \frac{I_0}{A_0 L^2}, \quad \phi'_1 = \phi_1 \frac{EI_0}{L}; \quad \phi'_2 = \phi_2 \frac{EI_1}{L},$$

The natural frequency of vibration is

$$\omega = \frac{\lambda}{L^2} \sqrt{\frac{EI_0}{\rho A_0}}$$

The governing functional is presented by Magrab (1979). The Ritz minimization procedure is presented by Gutierrez *et al.* (1991). The fundamental frequency parameters, λ , for

Special cases:

Parameters $\mu = 0$ and $\psi = 0$ correspond to a tapered beam without a tip body.
 Parameter $\psi = 0$ corresponds to a tapered beam with a tip mass but without a rotational effect.

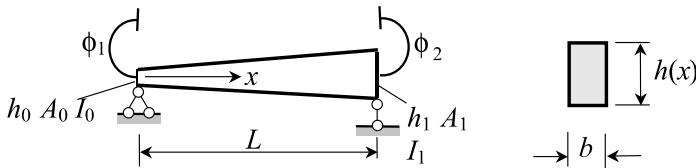

FIGURE 12.12. Tapered Timoshenko beam with ends elastically restrained against rotation.

tapered Timoshenko beams with different boundary conditions and parameters ϕ are presented in Tables 12.16(a)–(d). Calculations have been performed with Poisson coefficient $v = 0.3$ and shear coefficient $k = 0.833$.

In the tables are depicted numerical results obtained by (1) the optimized Ritz approach; (2) exact value and (3) by applying the finite element method, if the element was subdivided into 20 slices of constant thickness.

Special case:

* The case $\alpha = 0$ corresponds to a uniform beam.

12.3.3 Stepped Timoshenko beam with restrained at one end and guided at the other

The stepped beam with translational and rotational springs at one end and a guided support at the other is presented in Fig. 12.13, where K is the stiffness constant for a translational spring and ϕ is the flexibility constant for a rotational spring.

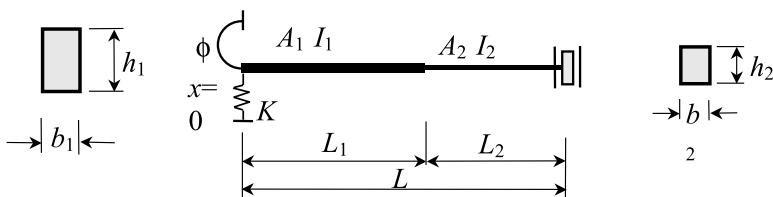

**FIGURE 12.13.** Stepped beam with an elastic support at one end and a guided support at the other.

The natural frequency of vibration is

$$\omega = \frac{\lambda}{L^2} \sqrt{\frac{EI_1}{\rho A_1}}$$

The first five natural frequency coefficients, λ , for stepped beams with different boundary conditions in terms of the dimensionless parameters are presented in Tables 12.17(a)–(d). The dimensionless parameters are

$$k' = \frac{KL^3}{EI_1}; \quad \phi' = \phi \frac{EI_1}{L}; \quad \eta = \frac{I_1}{A_1 L_1^2}; \quad \gamma_L = \frac{L_1}{L}; \quad \gamma_b = \frac{b_2}{b_1}; \quad \gamma_h = \frac{h_2}{h_1}$$

Calculations have been performed with the shear factor $k = 0.866$, and the Poisson coefficient $\nu = 0.3$ (Gutierrez *et al.*, 1990). This article also contains the governing Timoshenko differential equation, boundary and compatibility conditions as well as expressions for eigenfunctions.

12.4 TAPERED SIMPLY SUPPORTED BEAMS ON AN ELASTIC FOUNDATION

Consider a non-uniform simply supported beam resting on an elastic foundation; K_F is the foundation modulus. Three types of linear tapers are presented in Fig. 12.14. They are referred as (a) breadth taper, (b) depth taper, and (c) diameter taper.

The cross-sectional area $A(x)$ and the moment of inertia $I(x)$ may be expressed in common form

$$A(x) = A_c \left[1 - \beta + \frac{2x}{l} \beta \right]^{n_1}, \quad I(x) = I_c \left[1 - \beta + \frac{2x}{l} \beta \right]^{n_2}, \quad 0 \leq x \leq \frac{l}{2} \quad (12.23)$$

$$A(x) = A_c \left[1 + \beta - \frac{2x}{l} \beta \right]^{n_1}, \quad I(x) = I_c \left[1 + \beta - \frac{2x}{l} \beta \right]^{n_2}, \quad \frac{l}{2} \leq x \leq l \quad (12.24)$$

Parameter γ_{FT} depends of the types of taper. The various types of linear taper and the corresponding power parameters n_1 , n_2 as well as expressions for γ_{FT} for the first and second mode of vibration of simply supported beams are presented in Table 12.18 (Kanaka Raju, Venkateswara Rao, 1990). The dimensionless parameter of the foundation is

$$\gamma_F = \frac{K_F l^4}{\pi^4 E I_c}, \text{ where } K_F \text{ is the foundation modulus.}$$

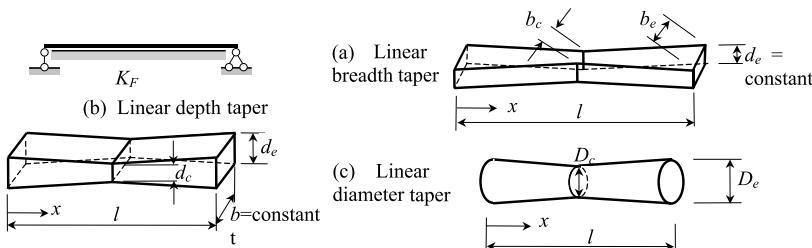

FIGURE 12.14. Non-uniform simply supported beam on an elastic foundation. Types of linear taper.

TABLE 12.18 Expressions for γ_{FT} for the first and second modes of vibration of tapered simply supported beams

Type of taper	β	n_1	n_2	Expression for γ_{FT}
Breadth taper	$\frac{b_c - b_e}{b_c}$	1	1	$-\frac{1}{\beta}(74.0220 - 59.0251\beta + 11.0070\beta^2)$
Depth taper	$\frac{d_c - d_e}{d_c}$	1	3	$-\frac{1}{\beta}(74.0220 - 135.0438\beta + 98.0387\beta^2 - 31.3730\beta^3 + 3.9184\beta^4)$
Diameter taper	$\frac{D_c - D_e}{D_c}$	2	4	$\frac{1}{\beta(0.1013 - 0.0380\beta)}(-3.75 + 9.8318\beta - 11.5007\beta^2 + 7.5146\beta^3 - 2.8629\beta^4 + 0.6049\beta^5 - 0.0567\beta^6)$

TABLE 12.19 Parameters γ_{FT} for the first and second mode of vibrations ($m = 1, 2$)

Taper parameter β	Breadth taper	Depth taper	Diameter taper
-0.05	1540.02	1620.5	827.77
-0.10	800.34	885.39	462.03
-0.15	554.16	643.95	343.33
-0.20	431.34	526.05	286.56

If the foundation parameter $\gamma_F < \gamma_{FT}$ then the beam vibrates in the first mode ($m = 1$), and if $\gamma_F > \gamma_{FT}$ then the beam vibrates in the second mode ($m = 2$), with the values of λ_f being the lowest, as listed in Table 12.20 later.

The subscripts c and e indicate the midpoint and ends for each of the beams. Several numerical results for parameters γ_{FT} for different taper parameters β and types of taper are presented in Table 12.19.

The non-dimensional frequency parameter is $\lambda^4 = \frac{\rho A_c \omega^2 l^4}{EI_c}$ and is presented for different types of taper in Table 12.20.

12.5 FREE-FREE SYMMETRIC PARABOLIC BEAM

A doubly symmetric parabolic beam is presented in Fig. 12.15.

The area of the cross-section and the moment of inertia are

$$A(x) = A_0(1 - cx^2) \quad (12.25)$$

$$I(x) = I_0(1 - bx^2) \quad (12.26)$$

TABLE 12.20 Tapered simply supported beams on elastic foundation: Frequency parameters λ^4 for different types of taper

Type of taper	Frequency parameter $\lambda^4 = a/b$
Breadth taper	$a = \pi^4 \left\{ m^4 \left[1 + \left(-\frac{1}{2} + \frac{1}{m^2\pi^2} - \frac{\cos m\pi}{m^2\pi^2} \right) \beta \right] + \gamma_F \right\}, \quad b = 1 - \left(\frac{1}{2} + \frac{\cos m\pi}{m^2\pi^2} - \frac{1}{m^2\pi^2} \right) \beta$
Depth taper	$a = \pi^4 \left\{ m^4 \left[1 + \left(-\frac{3}{2} + \frac{3}{m^2\pi^2} - \frac{3 \cos m\pi}{m^2\pi^2} \right) \beta + \left(1 - \frac{6}{m^2\pi^2} \right) \beta^2 + \left(-\frac{1}{4} + \frac{3}{m^2\pi^2} + \frac{6 \cos m\pi}{m^4\pi^4} - \frac{6}{m^4\pi^4} \right) \beta^3 \right] + \gamma_F \right\}$ $b = 1 + \left(-\frac{1}{2} + \frac{1}{m^2\pi^2} - \frac{\cos m\pi}{m^2\pi^2} \right) \beta$
Diameter taper	$a = \pi^4 \left\{ m^4 \left[1 + \left(-2 + \frac{2}{m^2\pi^2} - \frac{4 \cos m\pi}{m^2\pi^2} \right) \beta + 2 \left(1 - \frac{6}{m^2\pi^2} \right) \beta^2 + \left(-1 + \frac{12}{m^2\pi^2} + \frac{24 \cos m\pi}{m^4\pi^4} - \frac{24}{m^4\pi^4} \right) \beta^3 \right. \right. \\ \left. \left. + \left(\frac{1}{5} - \frac{4}{m^2\pi^2} + \frac{24}{m^4\pi^4} \right) \beta^4 \right] + \gamma_F \right\}$ $b = 1 + \left(-1 + \frac{2}{m^2\pi^2} - \frac{2 \cos m\pi}{m^2\pi^2} \right) \beta + \left(\frac{1}{3} - \frac{2}{m^2\pi^2} \right) \beta^2$

*Special cases:*If a simply supported beam has a uniform cross section then the taper parameter $\beta = 0$ and the frequency parameter is $\lambda^4 = \pi^4(m^4 + \gamma_F)$.If a simply supported beam has no elastic foundation then $\gamma_F = 0$ and $\lambda^4 = \pi^4 m^4$.

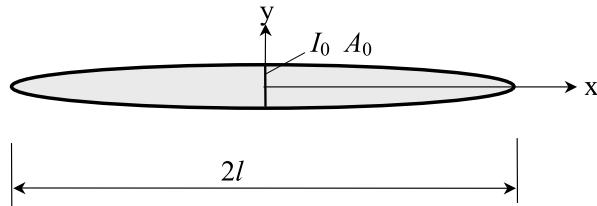

FIGURE 12.15. Free-free doubly symmetric parabolic beam.

The mode shape of vibration is

$$X_i(x) = \frac{\cosh k_i \cos k_i \frac{x}{l} + \cos k_i \cosh k_i \frac{x}{l}}{\sqrt{\cos^2 k_i + \cosh^2 k_i}} \quad (12.27)$$

where k_i are the roots of the equation

$$\tan k_i + \tanh k_i = 0, \quad k_1 = 0, \quad k_1 = 2.3650$$

The first root $k = 0$ corresponds to the motion of the beam without the bending effect.

Eigenfunctions $X_i(x)$ satisfy the boundary condition at free ends:

$$[X_i(x)]''_{x=l} = [X_i(x)]'''_{x=l} = 0 \quad (12.28)$$

The eigenfunctions that correspond to the found roots are

$$X_1(x) = \text{const}, \quad X_2(x) = \frac{k_2^2}{l^2} \frac{\cos k_2 \cosh k_2 \frac{x}{l} - \cosh k_2 \cos k_2 \frac{x}{l}}{\sqrt{\cos^2 k_2 + \cosh^2 k_2}} \quad (12.29)$$

Let $X_1(x) = \frac{1}{\sqrt{2}}$. In this case, the Ritz method yields the following expression for the fundamental frequency of vibration (Morrow, 1905; Krasnoperov, 1916; Timoshenko and Gere, 1961)

$$\omega = \sqrt{\frac{\alpha}{\beta_{22}} \frac{1}{1 - \frac{\beta_{12}^2}{\beta_{11}\beta_{22}}}} \sqrt{\frac{I_0 E}{A_0 \rho}} \quad (12.30)$$

where

$$\alpha = \int_{-l}^{+l} (1 - bx^2)(X_2'')^2 dx \quad \beta_{ij} = \int_{-l}^{+l} (1 - cx^2) X_i X_j dx \quad (12.31)$$

Substitution of expression (12.29) into (12.31) leads to the following results

$$\alpha = \frac{31.28}{\beta} (1 - 0.087bl^2) \\ \beta_{11} = l(1 - 0.333cl^2); \quad \beta_{12} = 0.297cl^3; \quad \beta_{22} = l(1 - 0.481cl^2)$$

NON-UNIFORM ONE-SPAN BEAMS

CHAPTER 13

OPTIMAL DESIGNED BEAMS

Chapter 13 is devoted to the optimal design of vibrating one-span beams. Two main problems are discussed.

1. The volume–frequency problem: find a configuration of the cross-sectional area $A(x)$ along the beam for the minimum (or maximum) frequency ω of a beam, if the volume of the beam V_0 is given.
2. The frequency–volume problem: find a configuration of the cross-sectional area $A(x)$ for the minimum (or maximum) volume V of a beam, if frequency $\omega = \omega_0$ is given.

The Bernoulli–Euler and Timoshenko beam theories are applicable. Analytical and numerical results for a beam with classical boundary conditions are presented. The maximum principle of Pontryagin has been applied.

NOTATION

$A(x)$	Cross-sectional area of a beam
E	Modulus of elasticity of the beam material
EI	Bending stiffness
h, b, r	Geometrical dimensions of the cross-section of the beam
H	Hamiltonian
$I(x)$	Moment of inertia of a cross-sectional area of a beam
k_1, k_2	Lagrange multipliers
l	Length of the beam
M, Q	Bending moment and shear force
t	Time
V	Volume of a beam
V_-, V_+	Lower and upper limit of the volume of a beam
x	Spatial coordinate
x, y, z	Cartesian coordinates
$X(x)$	Mode shape
$y(x)$	Lateral displacement of a beam
ρ, m	Density of material and mass per unit length of beam, $m = \rho A$
$\phi(x)$	Slope of a beam

ω	Circular natural frequency of a transverse vibration of a beam
ω^-, ω^+	Lower and upper bounds of the frequency vibration

13.1 STATEMENT OF A PROBLEM

The objects under study are non-uniform beams with different boundary conditions. The problem is to find the cross-sectional area distribution along the beam for a *minimum volume* of the beam, if the frequency of vibration is given. The dual problem is to find the cross-sectional area distribution along the beam for a *minimum frequency* of vibration of the beam if the volume of the beam is given.

Mathematical model. Differential equations of the transverse vibration presented in normal form are

$$\begin{aligned}\frac{dy}{dx} &= \phi \\ \frac{d\phi}{dx} &= -\frac{M}{EI} \\ \frac{dM}{dx} &= Q \\ \frac{dQ}{dx} &= -\omega^2 \rho A y\end{aligned}\tag{13.1}$$

where a vector of the state variables consists of the amplitude values of a lateral displacement y , slope ϕ , shear force Q and bending moment M with corresponding boundary conditions.

Boundary conditions may be presented in a common form

$$\begin{aligned}a_1y(0) + b_1Q(0) &= 0; & a_2\phi(0) + b_2M(0) &= 0 \\ a_3y(l) + b_3Q(l) &= 0; & a_4\phi(l) + b_4M(l) &= 0\end{aligned}\tag{13.2}$$

Coefficients a_i and b_i for different types of the supports are listed in Table 13.1.

Variable parameters. The cross-sectional area distribution along the beam, $A(x)$ (configuration), is the controlled variable.

TABLE 13.1. Boundary condition coefficients

	Pinned	Fixed	Free	Elastic support
Left end ($x = 0$)	$a_1 = b_2 = 1$ $a_2 = b_1 = 0$	$a_1 = a_2 = 1$ $b_1 = b_2 = 0$	$a_1 = a_2 = 0$ $b_1 = b_2 = 1$	$b_1 = b_2 = 1$ $a_1 = -k_{tr}$ $a_2 = k_{rot}$

Restrictions. The configuration $A(x)$ at any $x \in [0, l]$ must satisfy the condition $A_1(x) \leq A(x) \leq A_2(x)$, where $A_1(x)$ and $A_2(x)$ are given functions, and represent the lower and upper bounds of the cross-sectional area of the beam.

Criteria optimality. Optimal configuration $A(x)$ is such that it leads to the minimal volume of the beam:

$$V = \int A(x)dx \rightarrow \min$$

Problem $\omega \rightarrow V$. Find the configuration of $A(x)$ for the minimum (or maximum) volume $V = \int A(x) dx$ of a beam, if the frequency $\omega = \omega_0$ is given.

This problem may be solved if $\omega \in [\omega^-, \omega^+]$, where ω^- and ω^+ are the lower and upper bounds of the frequency of vibration according to the restriction.

Problem $V \rightarrow \omega$. Find the configuration $A(x)$ for the minimum (or maximum) frequency ω of a beam, if the volume of the beam, V_0 , is given

$$V = \int A(x)dx = V_0 \quad (13.3)$$

This problem may be solved if $V \in [V^-, V^+]$, where V^- and V^+ are the lower and upper limits of the volume of the beam according to the restriction.

TABLE 13.2. Presentation of moment of inertia for different cross-sections according to formula 13.5

Cross-section	Variable parameter	Constant parameter	Moment of inertia I vs area cross-section A
	b	h	$I = \frac{h^2}{12}A$
	h	b	$I = \frac{1}{12b^2}A^3$
	r	—	$I = \frac{1}{4\pi}A^2$
	β	α	$I = \gamma A$
	α	β	$I = \gamma A^3$
	η	α, β	$I = \gamma A^2$

The *Hamiltonian* is defined in terms of the vector of state variables and the criteria of optimality as follows

$$H = k_1 \left(\frac{M^2}{EI} + \omega^2 \rho A y^2 \right) - k_2 A \quad (13.4)$$

where k_1 and k_2 are the Lagrange multipliers.

The optimal configuration $A(x)$ will be expressed in terms of state variables from the condition of the maximum Hamiltonian (Pontryagin *et al.*, 1962).

The relation between a moment of inertia and cross-sectional area is conveniently expressed by

$$I = \gamma A^n \quad (13.5)$$

where γ is the proportional coefficient (Table 13.2). Parameters $n = 1$, $n = 2$ and $n = 3$ correspond to the variable width, homothetic cross-sections, and variable height, respectively.

13.2 COMMON PROPERTIES OF $\omega \rightarrow V$ AND $V \rightarrow \omega$ PROBLEMS

The fundamental properties of the optimal designed beams are distinctly and completely characterized by using the characteristic curve, which is presented in Fig. 13.1 (Grinev and Filippov, 1979).

The frequencies of vibrations ω_1 and ω_2 correspond to configurations

$$A(x) \equiv A_1(x) \quad \text{and} \quad A(x) \equiv A_2(x), \text{ respectively}$$

The minimum and maximum volumes of the beam, according to restrictions on the cross-sectional area are

$$V_- = \int_0^l A_1(x) dx; \quad V_+ = \int_0^l A_2(x) dx \quad (13.6)$$

If volume V_- is given, then configuration $A_1(x)$ is the solution of the problem $V \rightarrow \omega$ and its frequency vibration is ω_1 . If volume V_+ is given, then configuration $A_2(x)$ is the solution of the problem $V \rightarrow \omega$ and its frequency vibration is ω_2 .

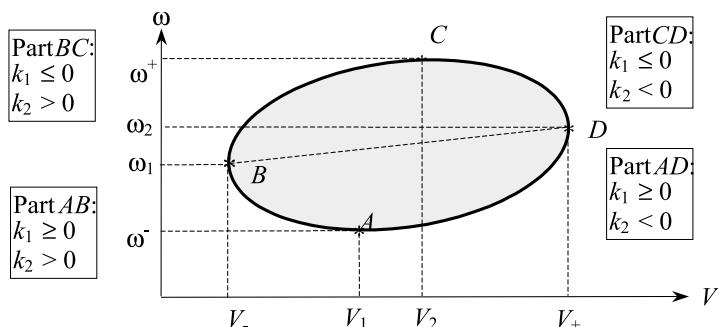

FIGURE 13.1. Characteristic curve. Notation and signs of Lagrange's multipliers.

The frequencies of vibrations ω^- , ω^+ present the minimal and maximal frequencies for the $V \rightarrow \omega$ problem, if we need only minimal and maximal frequencies without the condition $V = \text{constant}$. This means that, in the expression of the Hamilton function, the Lagrange multiplier k_2 equals zero.

Properties of the characteristic curve. The points A and C correspond to volumes V_1 and V_2 and eigenvalues ω^- and ω^+ . The points B and D correspond to eigenvalues ω_1 and ω_2 and volumes V_- and V_+ . The line BD corresponds to a uniform beam.

Problem $\omega \rightarrow V$. Part ABC corresponds to minimal volumes.

Part CDA corresponds to maximal volumes.

Problem $V \rightarrow \omega$. Part BCD corresponds to maximal eigenvalues.

Part BAD corresponds to minimal eigenvalues.

Types of solution. The problem of maximal eigenvalues, if the volume of the beam is given, has a continuous solution (see Figs. 13.2–13.5).

The problem of minimal eigenvalues, if the volume of the beam is given, has a discontinuous solution (see Figs. 13.2–13.5).

13.3 ANALYTICAL SOLUTION $\omega \rightarrow V$ AND $V \rightarrow \omega$ PROBLEMS

The optimal configuration $A(x)$ may be expressed in terms of state variables.

Continuous solution, $k_1 < 0$. This condition corresponds to the part BCD of the characteristic curve

$$A(x) = \begin{cases} A_2, & b \leq 0 \\ A_2, & A \geq A_2, \quad b > 0 \\ \left(\frac{n|k_1|M^2}{\gamma b E} \right)^{1/1+n}, & A_1 \leq A \leq A_2, \quad b > 0 \\ A_1, & A \leq A_1, \quad b > 0 \end{cases} \quad (13.7)$$

where $b = |k_1|\omega^2\rho y^2 + k_2$; parameter n is listed in Table 13.2.

Discontinuous solution, $k_1 \geq 0$. This condition corresponds to the part BAD of the characteristic curve

$$A(x) = \begin{cases} A_1, & k_1 M^2 \geq \gamma E \xi (b - 2k_2) \\ A_2, & k_1 M^2 < \gamma E \xi (b - 2k_2) \end{cases} \quad (13.8)$$

where

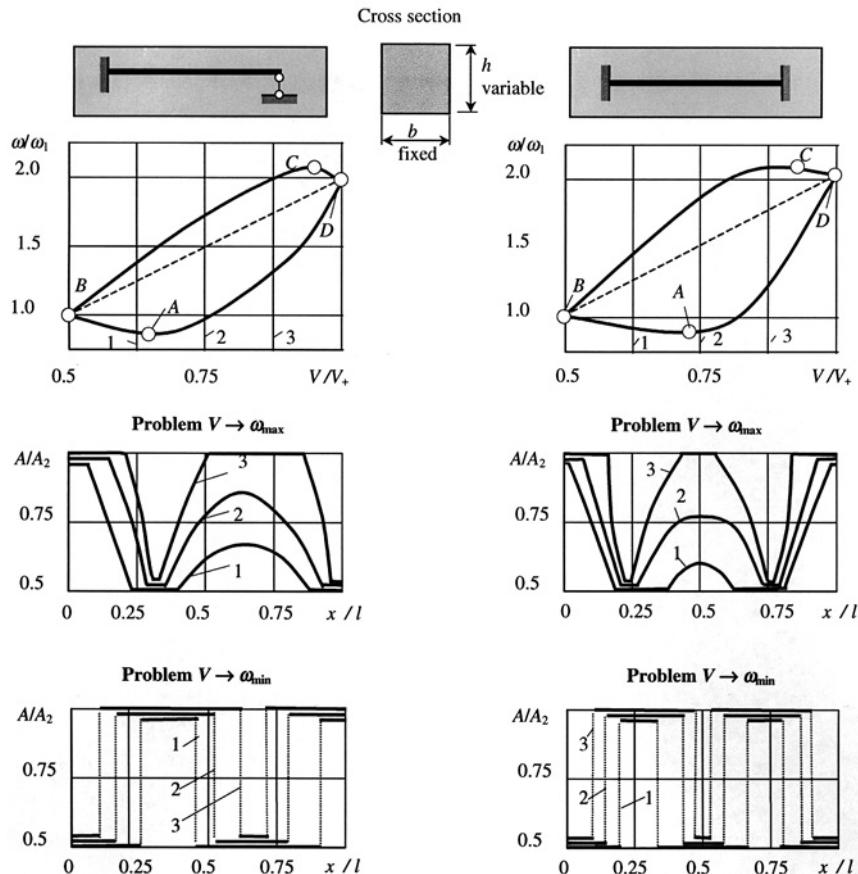

$$\xi = A_1^n A_2^n \frac{A_2 - A_1}{A_2^n - A_1^n}$$

The numerical procedures for finding the optimal configuration and the location of the points of the switch were developed and comprehensively discussed by Grinev and Filippov (1979).

The properties of the solution are presented in Table 13.3.

TABLE 13.3. Properties of continuous and discontinuous solutions for $\omega \rightarrow V$ and $V \rightarrow \omega$ problems

Continuous solution ($k_1 < 0$)	Discontinuous solution ($k_1 \geq 0$)
1. Maximum ω , if $V = \text{constant}$	1. Minimum ω , if $V = \text{constant}$
2. Minimum V , if $\omega \in [\omega_1 - \omega^+]$	2. Minimum V , if $\omega \in [\omega^- - \omega_1]$
3. Maximum V , if $\omega \in [\omega_2 - \omega^+]$	3. Maximum V , if $\omega \in [\omega^- - \omega_2]$

**FIGURE 13.2(a).** Optimal designed cantilever and simply-supported beams. Cross-section: rectangle; width $b = 0.02 \text{ m}$; height h is variable (parameter of cross-section $n = 3$). Length of a beam $l = 1.2 \text{ m}$. Restriction: $A_1 = 4 \times 10^{-4} \text{ m}^2$, $A_2 = 2A_1$. Material: $E = 1.96 \times 10^{11} \text{ N/m}^2$, $\rho = 7.8 \times 10^3 \text{ kg/m}^3$.

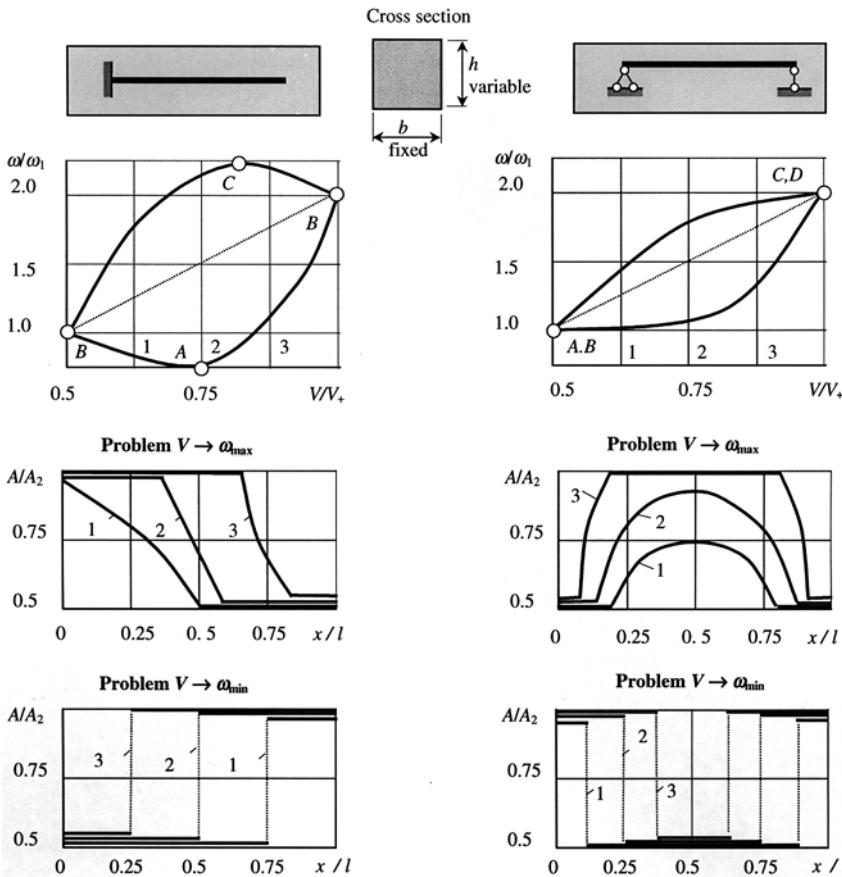

FIGURE 13.2(b). Optimal designed clamped-pinned and clamped-clamped beams. Cross-section rectangle; width $b = 0.02$ m; height h is variable (parameter of cross-section $n = 3$). Length of a beam $l = 1.2$ m. Restriction: $A_1 = 4 \times 10^{-4}$ m 2 , $A_2 = 2A_1$. Material: $E = 1.96 \times 10^{11}$ N/m 2 , $\rho = 7.8 \times 10^3$ kg/m 3 .

13.4 NUMERICAL RESULTS

The numerical results of optimal designed beams with different boundary conditions are presented in Figs. 13.2–13.4, (Grinev and Filippov, 1979). There are characteristic curves for fundamental frequencies of vibration in the dimensionless coordinates V/V_+ and ω/ω_1 and the corresponding optimal configuration A/A_2 in terms of x/l for different volumes (lines 1, 2, 3) of the beam. The continuous solution corresponds to the problem $V \rightarrow \omega_{\max}$ and the discontinuous one corresponds to the problem $V \rightarrow \omega_{\min}$.

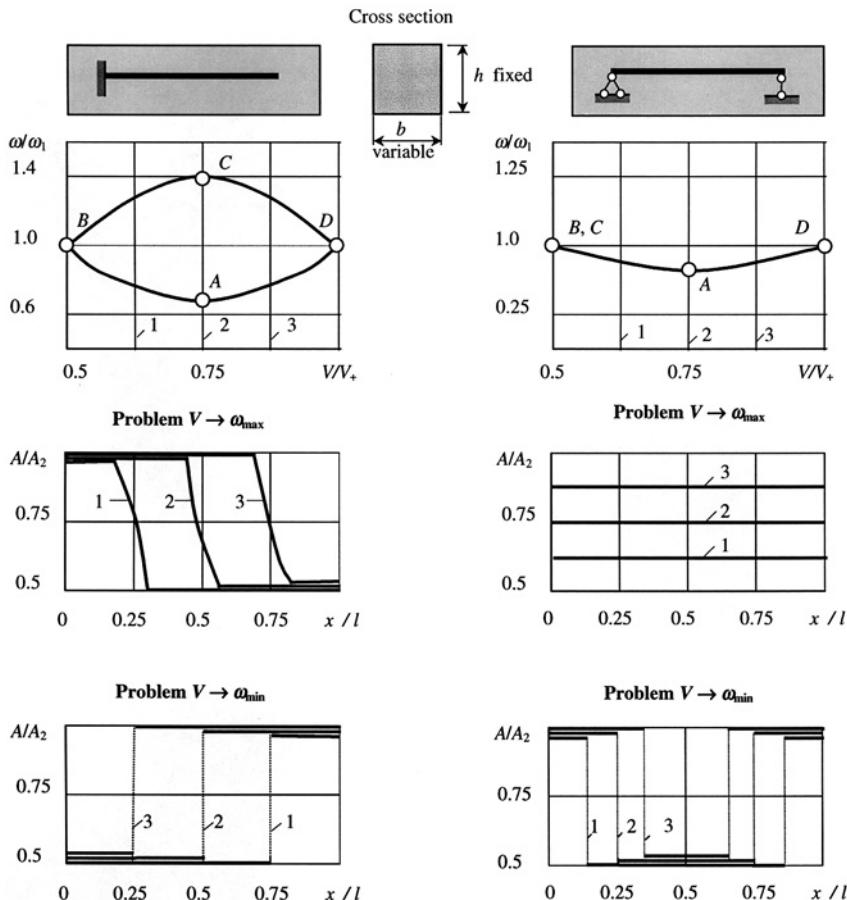

FIGURE 13.3(a). Optimal designed cantilever and simply-supported beams. Cross-section: rectangle; height $h = 0.02$ m; width b is variable (parameter of cross-section $n = 1$). Length of a beam $l = 1.2$ m. Restriction: $A_1 = 4 \times 10^{-4} \text{ m}^2$, $A_2 = 2A_1$. Material: $E = 1.96 \times 10^{11} \text{ N/m}^2$, $\rho = 7.8 \times 10^3 \text{ kg/m}^3$.

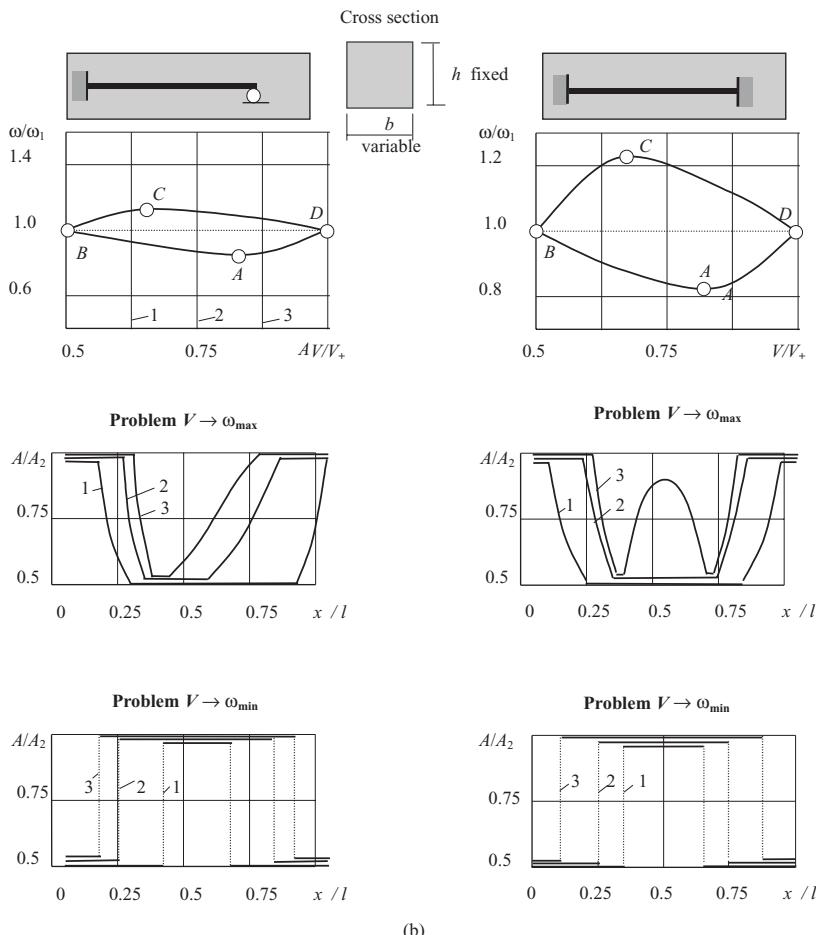

FIGURE 13.3(b). Optimal designed clamped-pinned and clamped-clamped beams. Cross-section: rectangle; height $h = 0.02 \text{ m}$; width b is variable (parameter of cross-section $n = 1$). Length of a beam $l = 1.2 \text{ m}$. Restriction: $A_1 = 4 \times 10^{-4} \text{ m}^2$, $A_2 = 2A_1$. Material: $E = 1.96 \times 10^{11} \text{ N/m}^2$, $\rho = 7.8 \times 10^3 \text{ kg/m}^3$.

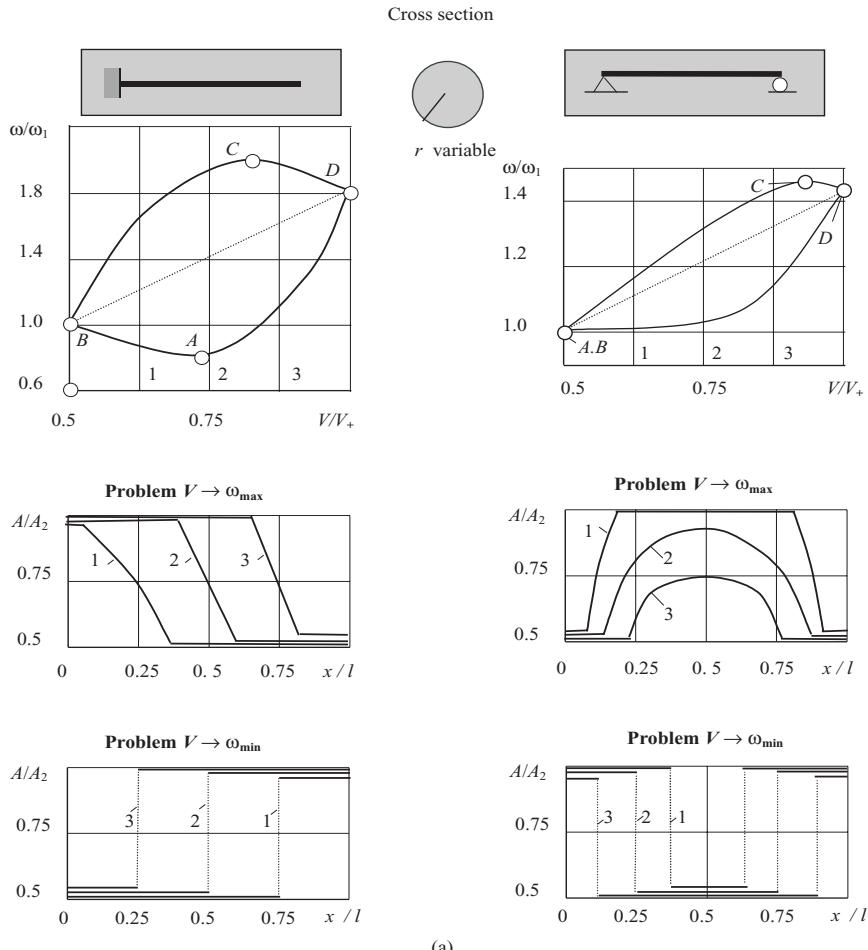

FIGURE 13.4(a). Optimal designed cantilever and simply-supported beams. Cross-section: circle; radius r is variable ($n = 2$). Restriction: $A_1 = 4 \times 10^{-4} \text{ m}^2$, $A_2 = 2A_1$. Length of a beam $l = 1.2 \text{ m}$. Material: $E = 1.96 \times 10^{11} \text{ N/m}^2$, $\rho = 7.8 \times 10^3 \text{ kg/m}^3$.

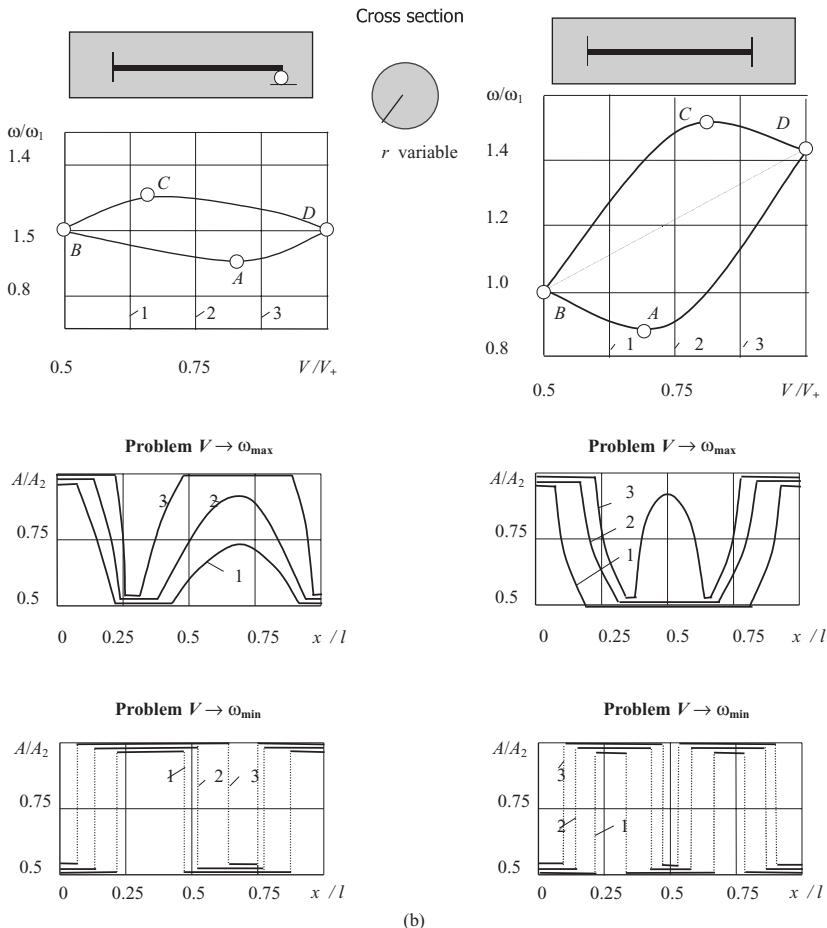

FIGURE 13.4(b). Optimal designed clamped-pinned and clamped-clamped beams. Cross-section: circle; radius r is variable ($n = 2$). Length of a beam $l = 1.2$ m. Restriction: $A_1 = 4 \times 10^{-4} \text{ m}^2$, $A_2 = 2A_1$. Material: $E = 1.96 \times 10^{11} \text{ N/m}^2$, $\rho = 7.8 \times 10^3 \text{ kg/m}^3$.

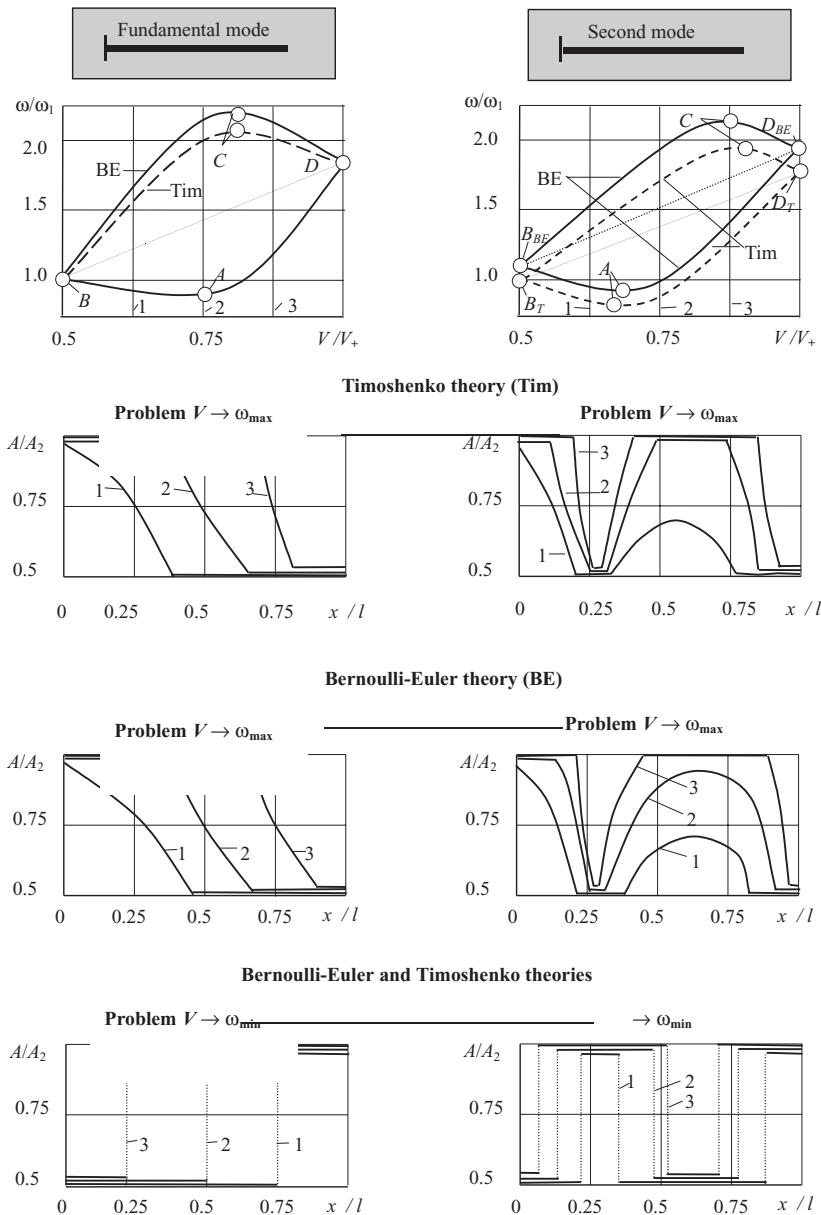

FIGURE 13.5. Optimal designed cantilever beam. Length of a beam $l = 1.2$ m. Cross-section: rectangle; $b = 0.02$ m; h is variable ($n = 3$). Material: $E = 1.96 \times 10^{11}$ N/m 2 , $\rho = 7.8 \times 10^3$ kg/m 3 . Restriction: $A_1 = 4 \times 10^{-4}$ m 2 , $A_2 = 2A_1$.

The numerical results for fundamental and second modes of vibration (clamped–free beam) are presented in Fig. 13.5. Lines I and II on the characteristic curve correspond to the Bernoulli–Euler and Timoshenko beam theories, respectively.

The numerical procedures developed and vast numerical results for longitudinal, bending and torsional vibrations were obtained by Grinev and Filippov (1971–1979).

CHAPTER 14

NONLINEAR TRANSVERSE VIBRATIONS

Chapter 14 is devoted to nonlinear transverse vibrations of beams. Static, physical and geometrical nonlinearities are discussed. In many cases, a method of reduction of nonlinear problems to linear ones with modified parameters is applied. This method is developed and presented by Bondar (1971). Some of the examples from the above mentioned book, are presented in this chapter. These are beams in magnetic fields, beams on nonlinear foundations, pipelines under moving liquids and internal pressure, etc. The frequency equations and the fundamental modes of vibrations are presented.

NOTATION

A	Cross-sectional area
A_F	Cross-sectional area of the rods
A_0	Open area of the pipeline
E, ρ	Young's modulus and density of the beam material
E_F, ρ_F	Young's modulus and density of the foundation material
EI	Bending stiffness
I_2, I_4	Cross-sectional area moments of inertia of order 2 and 4
k	Magnetic field parameter
l	Length of the beam
m, m_L	Mass per unit length of the beam and liquid
M	Bending moment
P	Internal pressure
r	Radius of gyration, $r^2 A = I$
t	Time
u	Longitudinal displacement of the rod
v, v_{cr}	Velocity and critical velocity of the moving liquid
w_0	Uniformly distributed force due to self-weight
x	Spatial coordinate
x, y, z	Cartesian coordinates
$X(x)$	Mode shape
y	Transversal displacement of the beam
β, β_F	Nonlinear parameter of the beam and foundation
σ, ε	Stress and strain of the beam material
ω	Natural frequency

14.1 ONE-SPAN PRISMATIC BEAMS WITH DIFFERENT TYPES OF NONLINEARITY

14.1.1 Static nonlinearity

The uniform beam rests on two immovable end supports, so displacements in the longitudinal direction of the beam at the support points are impossible, and the axial force N , e.g. thrust, is the response due to a vibration (Fig. 14.1). (Bondar', 1971; Lou and Sikarskie, 1975; Filin, 1981).

Fundamental relationships. Axial deformation and strain

$$\Delta l = \int_0^l \varepsilon(x) dx = \frac{1}{2} \int_0^l \left(\frac{\partial y}{\partial x} \right)^2 dx, \quad \varepsilon_{avr} = \frac{\Delta l}{l} = \frac{1}{2l} \int_0^l \left(\frac{\partial y}{\partial x} \right)^2 dx \quad (14.1)$$

The length of the curve, axial force and bending moment are

$$S = \int_0^l \sqrt{1 + \left(\frac{dy}{dx} \right)^2} dx \approx \int_0^l \left[1 + \left(\frac{dy}{dx} \right)^2 \right] dx, \quad (14.2)$$

$$N = EA\varepsilon_{avr} = \frac{EA}{2l} \int_0^l \left(\frac{\partial y}{\partial x} \right)^2 dx, \quad M = M_0 - Ny \quad (14.3)$$

where M_0 is the bending moment due to the transverse inertial force only.

Differential equation of transverse vibration. The governing differential equation is

$$EI \frac{\partial^4 y}{\partial x^4} - \frac{EA}{2l} \frac{\partial^2 y}{\partial x^2} \left[\int_0^l \left(\frac{\partial y}{\partial x} \right)^2 dx \right] + \rho A \frac{\partial^2 y}{\partial t^2} = 0 \quad (14.4)$$

The integral term in (14.4) represents the axial tension induced by the deflection and is the source of the nonlinearity in the problem.

Approximate solution

$$y(x, t) = X(x) \cos \phi(t), \quad \phi(t) = \omega t + \psi \quad (14.5)$$

where $X(x)$ = fundamental functions

$\phi(t)$ = phase functions

ω = frequency of vibration

ψ = initial phase angle

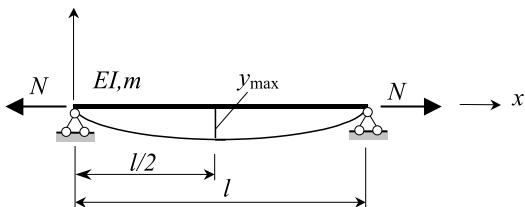

FIGURE 14.1. Beam on two immovable end supports.

Equation for normal functions

$$X^{IV} - \frac{3}{4}aX'' \int_0^l (X')^2 dx - b\omega^2 X = 0, \quad a = \frac{A}{2Il}, \quad b = \frac{m}{EI} \quad (14.6)$$

The solution of equation (14.6) may be presented as

$$X(x) = y_{\max} \sin \frac{\pi}{l} x$$

where y_{\max} is the transverse displacement of a beam at $x = 0.5l$.

Fundamental frequency of nonlinear vibration

$$\omega = \left(\frac{\pi}{l}\right)^2 \sqrt{\frac{1}{b} \left[1 + \left(\frac{l}{\pi}\right)^2 q_* \right]} \approx \left(\frac{\pi}{l}\right)^2 \sqrt{\frac{1}{b} \left[1 + \frac{1}{2} \left(\frac{l}{\pi}\right)^2 q_* \right]} = \frac{\pi^2}{l^2} \sqrt{\frac{EI}{m}} \left[1 + \frac{3}{8} \left(\frac{y_{\max}}{2r}\right)^2 \right], \quad (14.7)$$

where

$$q_* = \frac{3}{8} \frac{a}{l} \pi^2 y_{\max}^2, \quad r = \sqrt{\frac{I}{A}}$$

This result may be obtained in another way. Let the transverse displacement be

$$y(x, t) = y_{\max} T(t) \sin \frac{\pi x}{l}$$

The Bubnov–Galerkin procedure is

$$\int_0^l L(x, t) \sin \frac{\pi x}{l} dx = 0$$

where L is the left part of the differential equation of transverse vibration; this algorithm yields to Duffing's equation (Hayashi, 1964)

$$\ddot{T} + \frac{\pi^4 EI}{ml^4} \left[1 + \left(\frac{y_{\max}}{2r}\right)^2 T^2 \right] T = 0 \quad (14.8)$$

The fundamental frequency of vibration ω is as in equation 14.7.

If a free vibration is a response of a transverse shock on the beam, then the nonlinear mode shape and frequency vibration are

$$X(x) = -\frac{V_{\max}}{\omega_0} \sin \frac{\pi}{l} x$$

$$\omega = \omega_0 \left[1 + \frac{3}{8} \left(\frac{V_{\max}}{2r\omega_0}\right)^2 \right], \quad \omega_0 = \frac{\pi^2}{l^2} \sqrt{\frac{EI}{m}}$$

where V_{\max} is the initial velocity in the middle of the beam due to the transverse shock.

Note. The static nonlinearity does not have an influence on the mode shape of vibration.

14.1.2 Physical nonlinearity

Hook's law cannot be applied to the material of the beam.

Hardening nonlinearity. The 'stress-strain' relationship for the material of the beam is

$$\sigma = E\varepsilon + \beta\varepsilon^3 \quad (14.9)$$

where σ , ε are the stress and strain of the beam's material and β is the nonlinear parameter of the beam's material.

Bending moment

$$M = -y''[EI_2 + \beta I_4(y'')^2]$$

The moment of inertia of the cross-sectional area of the order n is

$$I_n = \int_{(A)} z^n \, dA \quad (14.10)$$

where z is the distance from a neutral axis.

For a rectangular cross section, $b \times h$:

$$I_2 = \frac{bh^3}{12}, \quad I_4 = \frac{bh^5}{80}$$

for a circular section of diameter d

$$I_2 = \frac{\pi d^4}{64}, \quad I_4 = \frac{\pi d^6}{512}$$

for a pipe with inner and outer diameters d and D , respectively

$$I_2 = \frac{\pi}{64}(D^4 - d^4), \quad I_4 = \frac{\pi}{512}(D^6 - d^6)$$

Differential equation

$$EI_2 \frac{\partial^4 y}{\partial x^4} + 6\beta I_4 \frac{\partial^2 y}{\partial x^2} \left(\frac{\partial^3 y}{\partial x^3} \right)^2 + 3\beta I_4 \left(\frac{\partial^2 y}{\partial x^2} \right)^2 \frac{\partial^4 y}{\partial x^4} + m \frac{\partial^2 y}{\partial t^2} = 0 \quad (14.11)$$

Approximate solution

$$y(x, t) = X(x) \cos \phi(t), \quad \phi(t) = \omega t + \psi \quad (14.12)$$

Equation for normal functions

$$X'''' \left[EI_2 + \frac{9}{4}\beta I_4(X'')^2 \right] + \frac{9}{2}\beta I_4 X''(X''')^2 - m\omega^2 X = 0 \quad (14.13)$$

Fundamental frequency of nonlinear vibration

$$\omega = \frac{\pi^2}{l^2\sqrt{b}} \frac{1}{\left(1 - \frac{3}{16}\lambda \frac{\pi^4}{l^4} y_{\max}^2\right)^2} \approx \frac{\pi^2}{l^2\sqrt{b}} \left(1 + \frac{6}{16}\lambda \frac{\pi^4}{l^4} y_{\max}^2\right) = \frac{\pi^2}{l^2} \sqrt{\frac{EI_2}{m}} \left(1 + \frac{27}{32} \frac{\pi^4 \beta I_4}{l^4 EI_2} y_{\max}^2\right) \quad (14.14)$$

The fundamental mode of vibration may be presented as

$$X = \frac{y_{\max}(1-s)\sin\frac{\pi}{l}x}{1-s\left(1+\cos^2\frac{\pi}{l}x\right)} \approx y_{\max}(1-s)\left[1+s\left(1+\cos^2\frac{\pi}{l}x\right)\right]\sin\frac{\pi}{l}x \quad (14.14a)$$

where

$$s = \frac{\lambda}{8} \left(\frac{\pi}{l}\right)^4 y_{\max}^2, \quad \lambda = \frac{9\beta I_4}{4EI_2}, \quad b = \frac{m}{EI_2}$$

Softening nonlinearity. The stress-strain relationship for the beam material is (Kauderer, 1958; Khachian and Ambartsumyan, 1981)

$$\sigma = E\varepsilon - \beta_1 E^3 \varepsilon^3 \quad (14.14b)$$

Displacement: $y(\xi, \tau) = X(\xi)Y(\tau)$, $\xi = \pi \frac{x}{l}$, $\tau = \omega t$.

The differential equation for the time function $Y(\tau)$

$$\frac{\partial^2 Y}{\partial \tau^2} + \frac{v^2 a^2}{\omega^2} Y \left(1 - \frac{1}{3}\lambda b_2 Y^2\right) = 0 \quad (14.15)$$

where

$$a^2 = \frac{\pi^4 EI_2}{ml^4}, \quad \lambda = \frac{3\pi^4 \beta_1 E^2}{l^4} \frac{I_4}{I_2}, \quad v^2 = \frac{1}{b_0} \int_0^\pi X''^2 d\xi,$$

$$b_0 = \int_0^\pi X^2 d\xi, \quad b_2 = \frac{1}{v^2 b_0} \int_0^\pi X''^4 d\xi$$

The moment of inertia of the order n is $I_n = \int_A z^n dA$.

Period of nonlinear vibration

$$T = \frac{1}{va} \left[1 + \frac{3}{8} \frac{\lambda b_2}{2} y_{\max}^2 + \frac{57}{256} \left(\frac{\lambda b_2}{3}\right)^2 y_{\max}^2 + \frac{315}{2048} \left(\frac{\lambda b_2}{3}\right)^6 y_{\max}^6 + \dots \right] \quad (14.16)$$

where y_{\max} is the fixed initial maximum lateral displacement of a beam.

Notes

1. Physical nonlinearity has an influence on the mode shape of vibration.
2. A hardening nonlinearity increases the frequency of vibration.
3. A softening nonlinearity decreases the frequency of vibration.

Special cases. The shape mode and period of the nonlinear vibration for beams with different boundary conditions may be calculated by the following formulas. (Khachian and Ambartsumyan, 1981)

Simply supported beam. Normal function

$$X(\xi) = \sin \xi, \quad b_0 = 0.5\pi, \quad v^2 = 1, \quad b_2 = 0.75$$

Nonlinear vibration period

$$T = T_0[1 + 0.09375\lambda y_{\max}^2 + 0.013916\lambda^2 y_{\max}^4 + 0.002403\lambda^3 y_{\max}^6 + \dots]$$

where $T_0 = 2\pi/a$ is the period of linear vibration.

Clamped-clamped beam. Fundamental function

$$X(\xi) = \frac{1}{1.61643} \left[\sin \frac{k}{\pi} \xi - 1.0178 \cos \frac{k}{\pi} \xi - \sinh \frac{k}{\pi} \xi + 1.0178 \cosh \frac{k}{\pi} \xi \right],$$

$$X_{\max} = 1, \quad k = 4.73$$

therefore $b_0 = 1.24542$, $v^2 = 5.1384$, $b_2 = 3.77213$.

Nonlinear vibration period

$$T = T_0[1 + 0.47152\lambda y_{\max}^2 + 0.35203\lambda^2 y_{\max}^4 + 0.30577\lambda^3 y_{\max}^6 + \dots]$$

where $T_0 = 2\pi/2.267a$.

Pinned-clamped beam. Normal function is

$$X(\xi) = \frac{1}{1.06676} \left[\sin \frac{k}{\pi} \xi + 0.027875 \sinh \frac{k}{\pi} \xi \right], \quad k = 3.927$$

where $X_{\max} = 1$ at $x = 0.421l$ from the pinned support.

For the above-mentioned expression X parameters b_0 , v^2 , b_2 and period of nonlinear vibration are

$$b_0 = 1.37911, \quad v^2 = 2.4423, \quad b_2 = 1.8116$$

$$T = T_0[1 + 0.22645\lambda y_{\max}^2 + 0.081193\lambda^2 y_{\max}^4 + 0.03387\lambda^3 y_{\max}^6 + \dots]$$

where the period of linear vibration is

$$T_0 = 2\pi/1.563a$$

Cantilever beam

$$X(\xi) = \frac{1}{2.7242} \left[\sin \frac{k}{\pi} \xi - 1.3622 \cos \frac{k}{\pi} \xi - \sinh \frac{k}{\pi} \xi + 1.3622 \cosh \frac{k}{\pi} \xi \right], \quad k = 1.875$$

$$b_0 = 0.78536, \quad v^2 = 0.1269, \quad b_2 = 0.074514$$

$$T = T_0[1 + 0.009314\lambda y_{\max}^2 + 0.000137\lambda^2 y_{\max}^4 + 0.0000023\lambda^3 y_{\max}^6 + \dots]$$

where $T_0 = 2\pi/0.362a$.

Notes

1. A hardening nonlinearity increases the frequency of vibration and has an influence on the fundamental shape of the mode of vibration.
2. A softening nonlinearity decreases the frequency of vibration and does not have an influence on the fundamental shape of the mode of vibration.

Example. The clamped-clamped beam has the following parameters: $l = 300 \text{ cm}$, $b = h = 40 \text{ cm}$. The beam material is concrete; a maximum strain of a concrete equals 0.003. Calculate the period of nonlinear vibration.

Solution. Expression (14.14) may be used if

$$\frac{d\sigma}{de} = E(1 - 3\beta_1 E^2 e^2) > 0$$

which leads to a maximum value of the nonlinear coefficient

$$\beta_1 = \frac{1}{3E^2 e^2}$$

In this case, the coefficient

$$\lambda = \frac{3\pi^4 \beta_1 E^2 I_4}{l^4} \frac{I_4}{I_2} = \frac{\pi^4}{l^4 e^2} \frac{I_4}{I_2} = \frac{\pi^4}{l^4 e^2} \frac{12h^2}{80}$$

If the maximum strain is 0.003 then the corresponding parameter

$$\lambda = 0.32 \text{ (1/cm}^2\text{)}$$

If $y_{\max} = l/200 \cong 1.5 \text{ cm}$, then the period of nonlinear vibration

$$T = T_0[1 + 0.47152\lambda y_{\max}^2 + 0.35203\lambda^2 y_{\max}^4 + 0.30577\lambda^3 y_{\max}^6 + \dots] = 1.6T_0$$

14.1.3. Geometrical nonlinearity (large amplitude vibration)

Geometrical nonlinearity occurs at large beam deflections.

Uniform beams. The differential equation of the free vibration of the geometrical nonlinear beam with different boundary conditions is given by Bondar (1971). The notation of the pinned-pinned beam with large transversal displacements is presented in Fig. 14.2.

The approximate fundamental frequency of vibration for a beam with various boundary conditions may be calculated by the formula

$$\omega \cong \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}} \left[1 + \frac{1}{4l} \int_0^l (X')^2 ds \right] \quad (14.17)$$

where λ is a frequency parameter, which depends from boundary condition (Table 5.3), and X is a mode shape of vibration for the linear problem.

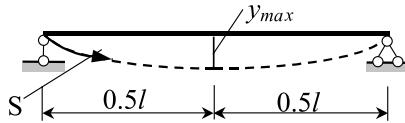

FIGURE 14.2. Simply supported beam with large transversal displacements.

Period of nonlinear vibration

$$T = \frac{2\pi}{\omega} \cong T_0 \left[1 - \frac{1}{4l} \int_0^l (X')^2 ds \right] \quad (14.18)$$

For calculation of the integral $\int_0^l (X')^2 ds$ for beams with different boundary conditions Table 5.8 may be used.

Special cases. The period of nonlinear vibration for beams with different boundary conditions may be presented in the following form.

Pinned-pinned beam. The fundamental mode of vibration is

$$X(s) = y_{\max} \sin \frac{\pi s}{l}, \quad \text{so} \quad \int_0^l (X')^2 ds = \frac{\pi^2}{2l} y_{\max}$$

and the period of nonlinear vibration in terms of initial maximum displacement is

$$T = T_0 \left[1 - \frac{\pi^2}{8} \left(\frac{y_{\max}}{l} \right)^2 \right]$$

Cantilever beam. The fundamental mode of vibration is

$$X(s) = \frac{1}{2} y_{\max} \left[\cosh \frac{\alpha s}{l} - \cos \frac{\alpha s}{l} - 0.734 \left(\sinh \frac{\alpha s}{l} - \sin \frac{\alpha s}{l} \right) \right],$$

$$\alpha = 1.875, \quad \text{so} \quad \int_0^l (X')^2 ds = \frac{\pi^2}{2l} y_{\max}$$

and the period of nonlinear vibration

$$T = T_0 \left[1 - \frac{1}{8} \left(\frac{y_{\max}}{l} \right)^2 \right]$$

Free-free beam. The period of nonlinear vibrations is

$$T = T_0 \left[1 - 1.55 \left(\frac{y_{\max}}{l} \right)^2 \right]$$

where T_0 is the period of vibration of the linear problem; and y_{\max} is the maximum lateral displacement of the middle point for a pinned-pinned beam and free-free beam and at the free end for a cantilever beam.

Note. Geometrical nonlinearity decreases the period of vibration and does have an influence on the fundamental shape of the mode of vibration.

Tapered beams. Table 14.1 present the types of linear tapered beams: breadth taper, depth taper, and diameter taper and their characteristics.

The mass per unit length m and the moment of inertia I of the tapered beams

$$\begin{aligned} m &= m_R \left[1 - \varepsilon + \frac{\eta}{l} \varepsilon \right]^{n_1} \\ I &= I_R \left[1 - \varepsilon + \frac{\eta}{l} \varepsilon \right]^{n_2} \end{aligned} \quad (14.19)$$

where $\eta = s/l$.

TABLE 14.1. Types of linear tapered beams

Type of taper	Geometry of tapered beams	Taper parameter ε	n_1	n_2
Linear breadth taper		$1 - \frac{B_T}{B_R}$	1	1
Linear depth taper		$1 - \frac{D_T}{D_R}$	1	3
Linear diameter taper		$1 - \frac{D_T}{D_R}$	2	4

Numerical results. The governing equations for the geometry of the nonlinear vibration of the beam take into account both the axial and transverse inertia terms. The numerical method had been applied.

Free-free tapered beam (Nageswara Rao and Venkateswara Rao, 1990). A free-tapered beam with large displacements is presented in Fig. 14.3, where l is a length of the beam and α is a slope at the tip.

The frequency of vibration may be calculated by

$$\omega = \frac{\lambda}{l^2} \sqrt{\frac{EI_R}{m_R}} \quad (14.20)$$

where subscript R denotes characteristics at the root of the beam.

Fundamental natural frequency parameters, λ , for different types of taper are presented in Table 14.2. Here, ε is a tapered parameter and α° is the slope at the tip.

^{*} Linear problem.¹ Table I2.2 for cases $\lambda = 1 - \varepsilon$.² Table I2.5 for cases $\delta = 1 - \varepsilon$.

Cantilever tapered beam (Nageswara Rao and Venkateswara Rao, 1988). A cantilever tapered beam with large displacements is presented in Fig. 14.4, where l is the length of the beam and α is the slope at the tip.

The frequency of vibration may be calculated by formula (14.20). Amplitude vibrations x_T , y_T and fundamental parameter λ for different types of taper are presented in Table 14.3; ε is a tapered parameter and α° is the slope at the tip.

14.2 BEAMS IN A MAGNETIC FIELD

14.2.1 Physical nonlinear beam in a nonlinear magnetic field

A uniform simply-supported beam in a magnetic field is presented in Fig. 14.5.

Types of nonlinearity

- Physical nonlinearity: stress-strain relation for a beam material

$$\sigma = E\varepsilon + \beta\varepsilon^3 \quad (14.21)$$

- Nonlinearity of the magnetic field: attractive force of the magnetic field

$$q_M = k \frac{ay}{(a^2 - y^2)^2} \approx k \frac{y}{a^3} \left(1 + 2 \frac{y^2}{a^2}\right), \quad (y \ll a) \quad (14.22)$$

where a = distance between beam and magnet

y = transverse displacement of a beam

k = proportional coefficient (k = constant)

Differential equation of the transverse vibration

$$EI_2 \frac{\partial^4 y}{\partial x^4} + 6\beta I_4 \frac{\partial^2 y}{\partial x^2} \left(\frac{\partial^3 y}{\partial x^3}\right)^2 + 3\beta I_4 \left(\frac{\partial^2 y}{\partial x^2}\right)^2 \frac{\partial^4 y}{\partial x^4} + m \frac{\partial^2 y}{\partial t^2} - k \frac{y}{a^3} \left(1 + 2 \frac{y^2}{a^2}\right) = 0 \quad (14.23)$$

This equation takes into account a physical nonlinearity of the beam material (a term with coefficient β) and the nonlinearity of the magnetic field (term ky^3/a^5).

Bending moment and deflection are related as follows:

$$M = -y''[EI_2 + \beta I_4(y'')^2]$$

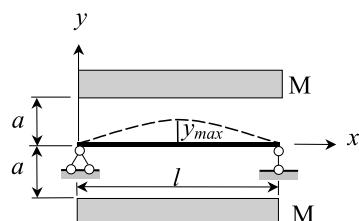

FIGURE 14.5. Simply-supported beam in the magnetic field.

Approximate solution

$$y(x, t) = X(x) \cos \phi(t), \quad \phi = \omega t + \psi$$

where $X(x)$ = fundamental mode of vibration

$\phi(t)$ = phase functions

ω = frequency of vibration

ψ = initial phase angle

Equation for fundamental normal function

$$X^{IV} \left[EI_2 + \frac{9}{4} \beta I_4 (X'')^2 \right] + \frac{9}{2} \beta I_4 X'' (X''')^2 - \left(m\omega^2 + \frac{k}{a^3} \right) X - \frac{3k}{2a^5} X^3 = 0 \quad (14.24)$$

Frequency of vibration

$$\omega \approx \sqrt{\frac{1}{m} \left\{ \left(\frac{\pi}{l}\right)^4 EI_2 \left[1 + \frac{3y_{\max}^2}{8EI_2} \left(\frac{9\pi^4\beta I_4}{2l^4} - \frac{kl^4}{\pi^4 a^5} \right) \right] - \frac{k}{a^3} \right\}} \quad (14.25)$$

Vibration is unstable, if

$$\left(\frac{\pi}{l}\right)^4 EI_2 \left[1 + \frac{3y_{\max}^2}{8EI_2} \left(\frac{9\pi^4\beta I_4}{2l^4} - \frac{3k^4}{\pi^4 a^5} \right) \right] \leq \frac{k}{a^3}$$

Fundamental mode shape of vibration

$$X \approx y_{\max} \left[1 + \frac{\lambda}{8} \left(\frac{\pi}{l}\right)^4 y_{\max}^2 \left(1 + \cos^2 \frac{\pi x}{l} \right) - \frac{k^*}{8} \left(\frac{l}{\pi}\right)^4 y_{\max}^2 \sin^2 \frac{\pi x}{l} \right] \sin \frac{\pi x}{l} \quad (14.26)$$

where parameters λ and k^* are as follows

$$\lambda = \frac{9\beta I_4}{4EI_2}, \quad k^* = \frac{3k}{2a^5 EI_2}$$

Different limiting cases are presented in Table 14.4.

14.2.2 Geometrical nonlinear beam in a nonlinear magnetic field

Consider a simply supported beam with a large displacement placed in a nonlinear magnetic field (Fig. 14.5). The attractive force of the magnetic field ($k = \text{const}$)

$$q_M = k \frac{ay}{(a^2 - y^2)^2} \approx k \frac{y}{a^3} \left(1 + 2 \frac{y^2}{a^2} \right), \quad (y \ll a)$$

For moderately large displacements, the differential equation for the fundamental mode of vibration is

$$EI_2 X^{IV} - \left(m\omega^2 + \frac{k}{a^2} \right) X - \frac{3k}{2a^5} X^3 = 0 \quad (14.27)$$

TABLE 14.4. Physical nonlinear beam in nonlinear magnetic field and its limiting cases

No.	Description of problem	Conditions
1	Nonlinear physical beam in a linear magnetic field	$k/a^5 = 0$
2	Linear physical beam in a nonlinear magnetic field	$\beta = 0$
3	Linear physical beam in a linear magnetic field	$k/a^5 = 0$ and $\beta = 0$
4	Linear physical beam without a magnetic field	$k = 0$ and $\beta = 0$ (Table 5.3)

The frequency of vibration

$$\omega = \sqrt{\frac{1}{m\psi} \left\{ \left(\frac{\pi}{l}\right)^4 EI \left(1 - \frac{3}{8EI\pi^4 a^5} \frac{k\psi l^4}{y_{\max}^2}\right) - \frac{k\psi}{a^3} \right\}}, \quad \psi = 1 - \left(\frac{\pi}{2l} y_{\max}\right)^2 \quad (14.28)$$

where y_{\max} is the fixed initial maximum lateral displacement of the beam.

Vibration is unstable, if

$$\left(\frac{\pi}{l}\right)^4 EI \left(1 - \frac{3}{8EI\pi^4 a^5} \frac{k\psi l^4}{y_{\max}^2}\right) \leq \frac{k\psi}{a^3}$$

For the cantilever beam, coefficient $\psi = 1$.

Special cases

- Geometrical nonlinear beam in a linear magnetic field: $k/a^5 = 0$. In this case, the frequency of vibration

$$\omega = \sqrt{\frac{1}{m\psi} \left\{ \left(\frac{\pi}{l}\right)^4 EI - \frac{k\psi}{a^3} \right\}}$$

- Geometrical nonlinear beam without a magnetic field: $k = 0$ (Section 14.1.3). In this case, the frequency of vibration

$$\omega = \frac{\pi^2}{l^2} \sqrt{\frac{EI}{m\psi}}$$

14.3 BEAMS ON AN ELASTIC FOUNDATION

14.3.1 Physical nonlinear beams on massless foundations

Consider simply supported physically nonlinear beams resting on a massless foundation.

Types of nonlinearity

- Physical nonlinearity: the stress-strain relation for a beam material is presented by (14.21).

2. Nonlinearity of foundation: reaction of the foundation

$$q_F = -k_F y(1 + \beta_F y^2) \quad (14.29)$$

where y = transverse displacement of a beam

k_F = stiffness of a foundation

β_F = nonlinearity parameter of the foundation

Differential equation of the transverse vibration of the beam

$$EI_2 \frac{\partial^4 y}{\partial x^4} + 6\beta I_4 \frac{\partial^2 y}{\partial x^2} \left(\frac{\partial^3 y}{\partial x^3} \right)^2 + 3\beta I_4 \left(\frac{\partial^2 y}{\partial x^2} \right)^2 \frac{\partial^4 y}{\partial x^4} + m \frac{\partial^2 y}{\partial t^2} + k_F(1 + \beta_F y^2) = 0 \quad (14.30)$$

Moment of inertia of the order n may be calculated by formula (14.10).

Frequency of vibration

$$\omega = \sqrt{\frac{1}{m} \left\{ \left(\frac{\pi}{l} \right)^4 EI_2 \left[1 - \frac{3y_{\max}^2}{8EI_2} \left(\frac{9\pi^4 \beta I_4}{l^4} + \frac{k_F \beta_F l^4}{\pi^4} \right) \right] + k_F \right\}} \quad (14.31)$$

Different limiting cases are presented in Table 14.5

TABLE 14.5. Physical nonlinear beam on massless foundation and its limiting cases

No.	Description of problem	Conditions
1	Physical nonlinear beam without foundation	$k_F = 0$: (Section 14.1.2)
2	Linear elastic beam on a nonlinear foundation	$\beta = 0$
3	Nonlinear beam on a linear foundation	$\beta_F = 0$
4	Linear elastic beam on a linear foundation	$\beta = 0$ and $\beta_F = 0$ (Section 8.2.2)
5	Simply supported linear elastic beam without a foundation	$\beta = 0$ and $\beta_F = 0$, $k_F = 0$ (Table 5.3)

14.3.2 Physical nonlinear beam on a nonlinear inertial foundation

The physical nonlinear beam length l and mass m per unit length rest on a nonlinear elastic foundation. The stress-strain relation for a beam material is presented in formula (14.21). A nonlinear inertial foundation is a two-way communication one. A reaction to the foundation equals

$$q_F = -k_F y(1 + \beta_F y^2)$$

where y = transverse displacement of a beam

k_F = stiffness of a foundation

β_F = nonlinearity parameter of the foundation

The model of the foundation is represented as separate rods with the following parameters: modulus E_F , cross-sectional area $A_F = b_b \times 1$, and density of material ρ_F ; the length of the rods are l_0 and they are shown in Fig. 14.6.

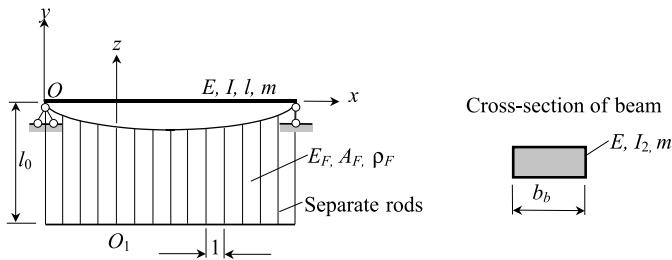

FIGURE 14.6. Mechanical model of nonlinear elastic foundation. Systems coordinates: for beam xOy ; for rods O_1z .

Reaction of the rods

$$q_0 = -E_F A_F \left\{ \frac{\partial u}{\partial z} \left[1 + \frac{\beta_F}{E_F} \left(\frac{\partial u}{\partial z} \right)^2 \right] \right\}_{z=l_0} \quad (14.32)$$

where u is the longitudinal displacement of the rod.

Differential equations

1. Longitudinal nonlinear vibration of the rods (Kauderer, 1958)

$$\frac{\partial^2 u}{\partial t^2} = a^2 \frac{\partial^2 u}{\partial z^2} \left[1 + \lambda \left(\frac{\partial u}{\partial z} \right)^2 \right] \quad (14.33)$$

where

$$a^2 = \frac{E_F A_F}{m_F} = \frac{E_F}{\rho_F}, \quad \lambda = 3 \frac{\beta_F}{E_F}$$

2. Transverse vibration of the beam

$$EI_2 \frac{\partial^4 y}{\partial x^4} + 6\beta I_4 \frac{\partial^2 y}{\partial x^2} \left(\frac{\partial^3 y}{\partial x^3} \right)^2 + 3\beta I_4 \left(\frac{\partial^2 y}{\partial x^2} \right)^2 \frac{\partial^4 y}{\partial x^4} + m \frac{\partial^2 y}{\partial t^2} + \left\{ E_F A_F \frac{\partial u}{\partial z} \left[1 + \frac{\beta_F}{E_F} \left(\frac{\partial u}{\partial z} \right)^2 \right] \right\}_{z=l_0} = 0 \quad (14.34)$$

where moments of inertia of the order n (I_2 and I_4) may be calculated by formula (14.10).

Approximate solution. Transverse displacement $y(x, t)$ of a beam and longitudinal displacement of rods $u(x, t)$ may be presented as

$$\begin{aligned} y(x, t) &= X(x) \cos \phi(t) \\ u(z, x, t) &= Z(z, x) \cos \phi(t) \end{aligned} \quad (14.35)$$

where $\phi = \omega t + \psi$.

The normal function for a pinned-pinned beam

$$X(x) = y_{\max} \sin \frac{\pi}{l} x$$

Approximate equations for normal functions. For longitudinal linear vibration of the rods after averaging (Bondar', 1971)

$$\frac{d^2 Z}{dz^2} + \left(\frac{\omega}{\alpha}\psi_z\right)^2 Z = 0 \quad (14.36)$$

where parameter

$$\psi_z = \sqrt{1 - 3\lambda \left(\frac{\omega y_{\max}}{4a}\right)^2 \delta} \approx 1 - \frac{3}{2} \lambda \left(\frac{\omega y_{\max}}{4a}\right)^2 \delta, \quad \delta = \frac{1 + \frac{a}{3\omega l_0} \sin \frac{2\omega}{a} l_0}{\left(\sin \frac{\omega}{a} l_0\right)^2}$$

For transverse nonlinear vibrations of the beam

$$X^{IV} \left[EI_2 + \frac{9}{4} \beta I_4 (X'')^2 \right] + \frac{9}{2} \beta I_4 X'' (X''')^2 + \left(\frac{\omega}{a} E_F A_F \psi_z \cot \frac{\omega}{a} \psi_z l_0 - m \omega^2 \right) X - \frac{3}{4} \beta_F A_F \psi_x^3 X^3 = 0 \quad (14.37)$$

where parameter

$$\psi_x = \frac{\omega}{\alpha} \psi_z \cot \frac{\omega}{\alpha} \psi_z l_0$$

Nonlinear frequency equation

$$\omega^2 b^2 - \frac{\omega}{\alpha} C \cot \frac{\omega}{\alpha} \psi_z l_0 = \left(\frac{\pi}{l}\right)^4 \left[1 + \frac{3}{16} \frac{y_{\max}^2}{EI_2} \left(\frac{9\pi^4 \beta I_4}{l^4} - \frac{l^4 \beta_F A_F}{\pi^4} \psi_x^3 \right) \right] \quad (14.38)$$

where parameter

$$C = \frac{E_F A_F}{EI_2} = \frac{E_F b_b}{EI_2}, \quad b^2 = \frac{m}{EJ_2}$$

Special case

Linear vibration: $y_{\max} = 0$ (Section 8.3.3). In this case a frequency equation becomes

$$\omega^2 b^2 - \frac{\omega}{\alpha} C \cot \frac{\omega}{\alpha} l_0 = \left(\frac{\pi}{l}\right)^4$$

- 1.** *Beam without an elastic foundation ($E_F = 0 \rightarrow C/a = 0$).* The frequency equation of the beam is

$$\left(\frac{\pi}{l}\right)^4 - b^2 \omega^2 = 0$$

and the fundamental frequency of vibration of the beam is $\omega = \frac{\pi^2}{l^2} \sqrt{\frac{EI_2}{m}}$.

- 2.** *Elastic foundation without a beam ($EI_2 = 0 \rightarrow b = \infty, C = \infty$).* The frequency equation of the longitudinal vibration of the rod is

$$\tan \gamma = \infty, \quad \gamma = \pi/2$$

and the fundamental frequency of the longitudinal vibration is

$$\omega = \frac{\pi}{2l_0} \sqrt{\frac{E_F}{\rho_F}}$$

This case corresponds to a longitudinal vibration of the clamped-free rods.

- 3.** *The beam is absolutely rigid ($EI_2 = 0 \rightarrow b = 0, C = 0$).* The frequency equation becomes

$$\tan \gamma = 0, \quad \gamma = \pi.$$

and the fundamental frequency of the longitudinal vibration is

$$\omega = \frac{\pi}{l_0} \sqrt{\frac{E_F}{\rho_F}}$$

This case corresponds to longitudinal vibration of the clamped-clamped rods.

14.4 PINNED-PINNED BEAM UNDER MOVING LIQUID

Consider a vertical pipeline, or a horizontal one, without initial deflections, carrying a moving liquid; the velocity of the liquid, V , and stiffness of the beam, EI , are constant. The quasi-static regime is discussed.

14.4.1 Static nonlinearity

The beam rests on two immovable supports (Fig. 14.7).

The distributed load on the beam is

$$w = -m \frac{\partial^2 y}{\partial t^2} - m_L \left(\frac{\partial^2 y}{\partial t^2} + V^2 \frac{\partial^2 y}{\partial x^2} \right) \quad (14.39)$$

where m and m_L are the mass per unit length of the beam and the mass of the moving liquid, respectively. The first term in equation (14.39) describes the inertial force of the

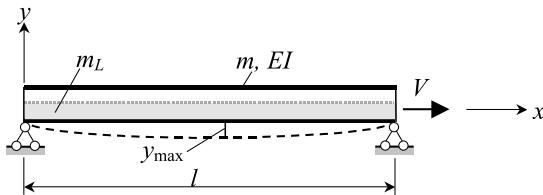

FIGURE 14.7. Pipeline under moving liquid. Quasi-static regime. Static nonlinearity.

beam. The first and second terms in the brackets take into account the relative and transfer forces of inertia of a moving liquid, respectively.

Differential equation of transverse vibration of the beam

$$\frac{\partial^4 y}{\partial x^4} + \frac{m + m_L}{EI} \frac{\partial^2 y}{\partial t^2} + \frac{\partial^2 y}{\partial x^2} \left[\frac{m_L V^2}{EI} - \frac{1}{2lr^2} \int_0^l \left(\frac{\partial y}{\partial x} \right)^2 dx \right] = 0 \quad (14.40)$$

where y is a transverse displacement of a beam; and $r^2 = I/A$, a square of the radius of gyration of a cross-section area.

This equation is approximate because it does not take into account the Coriolis inertia force. The solution of equation (14.40) may be presented in a form

$$y(x, t) = X(x) \cos \omega(t)$$

Equation for normal function

$$X'''' - \frac{m + m_L}{EI} \omega^2 X + X'' \left[\frac{m_L V^2}{EI} - \frac{3}{4} \cdot a \int_0^l (X')^2 dx = 0 \right], \quad a = \frac{1}{2lr^2} \quad (14.41)$$

The second term in the brackets takes into account the nonlinear effect.

The expression for the normal function

$$X(x) = y_{\max} \sin \frac{\pi x}{l}$$

leads to a fundamental nonlinear frequency of vibration

$$\omega_1 = \frac{\pi^2}{l^2} \sqrt{\frac{EI}{m + m_L}} \sqrt{1 + \frac{l^2}{\pi^2} \left[\frac{3}{4} \left(\frac{\pi y_{\max}}{2lr} \right)^2 - \frac{m_L V^2}{EI} \right]} \quad (14.42)$$

Condition of stability loss

$$\frac{l^2}{\pi^2} \left[\frac{3}{4} \left(\frac{\pi y_{\max}}{2lr} \right)^2 - \frac{m_L V^2}{EI} \right] = -1$$

First critical velocity

$$V_{1cr} = \frac{\pi}{l} \sqrt{\frac{EI}{m_L}} \sqrt{1 + 3 \left(\frac{y_{\max}}{4r} \right)^2} \approx \frac{\pi}{l} \sqrt{\frac{EI}{mL}} \left[1 + \frac{3}{2} \left(\frac{y_{\max}}{4r} \right)^2 \right]$$

Second frequency of vibration and critical velocity. These characteristics may be obtained by using the Bubnov–Galerkin method.

The mode shape

$$X(x) = y_{\max} \sin \frac{2\pi x}{l}, \quad \text{where } y_{\max} = y(0.25l)$$

which corresponds to the second frequency of vibration, and leads to the following expressions for the natural frequency of vibration and critical velocity

$$\omega_2 = \frac{4\pi^2}{l^2} \sqrt{\frac{EI}{m + m_L}} \sqrt{1 + \frac{l^2}{4\pi^2} \left[\frac{3}{4} \left(\frac{\pi y_{\max}}{lr} \right)^2 - \frac{m_L V^2}{EI} \right]}$$

$$V_{2\text{cr}} = \frac{2\pi}{l} \sqrt{\frac{EI}{m_L}} \sqrt{1 + 3 \left(\frac{y_{\max}}{2r} \right)} \approx \frac{2\pi}{l} \sqrt{\frac{EI}{m_L}} \left[1 + \frac{3}{2} \left(\frac{y_{\max}}{2r} \right)^2 \right]$$

For the linear problem $V_{2\text{cr}} = 2V_{1\text{cr}}$.

Special cases

1. Linear problem, if $y_{\max} = 0$.
2. If the Coriolis inertia force is taken into account, then the distributed load is

$$w = -m \frac{\partial^2 y}{\partial t^2} - m_L \left(\frac{\partial^2 y}{\partial t^2} + 2V \frac{\partial^2 y}{\partial t \partial x} + V^2 \frac{\partial^2 y}{\partial x^2} \right)$$

and the differential equation of the transverse vibration of the beam becomes

$$\frac{\partial^4 y}{\partial x^4} + \frac{m + m_L}{EI} \frac{\partial^2 y}{\partial t^2} + \frac{\partial^2 y}{\partial x^2} \left[\frac{m_L V^2}{EI} - \frac{A}{2I} \int_0^l \left(\frac{\partial y}{\partial x} \right)^2 dx \right] + \frac{2m_L V}{EI} \frac{\partial^2 y}{\partial x \partial t} = 0$$

In this case, the frequency of vibration is very close to the results that were obtained by using the expression for ω_1 .

14.4.2 Physical nonlinearity

Consider a simply supported beam carrying the moving load. The velocity of the liquid, V , and stiffness of the beam, EI , are constant (Fig. 14.8). The stress-strain relationship for the material of the beam $\sigma = E\varepsilon + \beta\varepsilon^3$. The initial deflection of the beam under self-weight is ignored. The quasi-static regime is discussed.

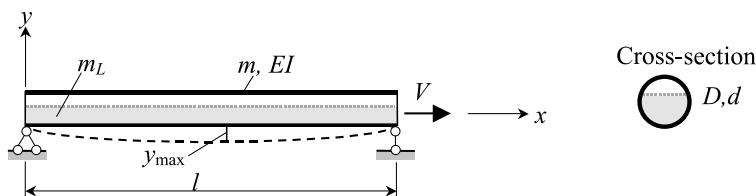

FIGURE 14.8. Pipeline under infinite moving liquid. Quasi-static regime.

The bending moment is

$$M = -y''[EI_2 + \beta I_4(y'')^2]$$

The second term in brackets describes the effect of physical nonlinearity.

Differential equation of the transverse vibration

$$EI_2 \frac{\partial^4 y}{\partial x^4} + 6\beta I_4 \frac{\partial^2 y}{\partial x^2} \left(\frac{\partial^3 y}{\partial x^3} \right)^2 + 3\beta I_4 \left(\frac{\partial^2 y}{\partial x^2} \right)^2 \frac{\partial^4 y}{\partial x^4} + (m + m_L) \frac{\partial^2 y}{\partial t^2} + m_L V^2 \frac{\partial^2 y}{\partial x^2} = 0 \quad (14.43)$$

where m and m_L are the mass per unit length of the beam and the mass of the moving liquid, respectively. Expressions for the cross-sectional area moments of inertia I_2 and I_4 are presented in Section 14.1.2.

The expression for transverse displacement in the form

$$y(x, t) = X(x) \cos \omega(t)$$

leads to the following equation for a normal function

$$X'''' \left[EI_2 + \frac{9}{4} \beta I_4 (X'')^2 \right] + X'' \left[m_L V^2 + \frac{9}{2} \beta I_4 (X''')^2 \right] - m \omega^2 X = 0 \quad (14.44)$$

The approximate presentation of a normal function

$$X(x) = y_{\max} \sin \frac{\pi x}{l}$$

leads to the following frequency of vibration of the beam under the quasi-static regime

$$\omega = \frac{\pi^2}{l^2} \sqrt{\frac{EI_2}{m + m_L}} \sqrt{1 + \frac{l^2}{\pi^2} \left(\frac{27 \beta I_4 \pi^6}{16 EI_2 l^6} y_{\max}^2 - \frac{m_L V^2}{EI_2} \right)} \quad (14.45)$$

The first critical velocity

$$V_{\text{cr}} = \frac{\pi}{l} \sqrt{\frac{EI_2}{m_L}} \sqrt{1 + \frac{27 \beta I_4 \pi^4}{16 EI_2 l^4} y_{\max}^2} \approx \frac{\pi}{l} \sqrt{\frac{EI_2}{m_L}} \left(1 + \frac{27 \beta I_4 \pi^4}{32 EI_2 l^4} y_{\max}^2 \right)$$

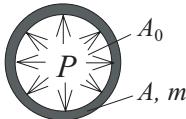

Special case. Consider a physically linear beam under the quasi-static regime. In this case, the parameter nonlinearity $\beta = 0$ and the expression for the linear frequency of vibration and critical velocity are

$$\omega = \frac{\pi^2}{l^2} \sqrt{\frac{EI_2}{m + m_L}} \sqrt{1 - \frac{l^2 m_L V^2}{\pi^2 EI_2}}$$

$$V_{\text{cr}} = \frac{\pi}{l} \sqrt{\frac{EI_2}{m_L}}$$

14.5 PIPELINE UNDER MOVING LOAD AND INTERNAL PRESSURE

A vertical pipeline or a horizontal one without initial deflections is kept under moving liquid and internal pressure P ; the velocity of the liquid V and stiffness of the beam EI are constant. The quasi-static regime is discussed.

Distributed load on a beam

$$w = -m \frac{\partial^2 y}{\partial t^2} - m_L \left(\frac{\partial^2 y}{\partial t^2} + 2V \frac{\partial^2 y}{\partial t \partial x} \right) - (m_L V^2 + PA_0) \frac{\partial^2 y}{\partial x^2} \quad (14.46)$$

where m and m_L are the mass per unit length of the beam and the mass of the moving liquid, respectively, and A_0 is the open cross-section.

The first term describes the inertial force of the beam. The first terms in the first and second brackets take into account relative and transfer forces of inertia of a moving liquid, respectively. The second terms in the first and second brackets take into account Coriolis inertia force of a moving liquid and interval pressure.

14.5.1 Static nonlinearity

The beam rests on two immovable supports (Fig. 14.7).

Frequency of vibration

$$\omega = \frac{\pi^2}{l^2} \sqrt{\frac{EI}{m+m_L}} \sqrt{1 + \frac{l^2}{\pi^2} \left[\frac{3}{4} \left(\frac{\pi y_{\max}}{2lr} \right)^2 - \frac{1}{EI} (m_L V^2 + PA_0) \right]} \quad (14.47)$$

Critical velocity

$$V_{\text{cr}} = \sqrt{\frac{1}{m_L} \left\{ EI \frac{\pi^2}{l^2} \left[1 + \frac{3}{4} \left(\frac{y_{\max}}{2r} \right)^2 \right] - PA_0 \right\}}, \quad r = \sqrt{\frac{T}{A}}$$

Special case. Consider a statically linear beam under an infinite moving load and internal pressure. In this case $y_{\max} = 0$ and the expressions for the linear frequency of vibration and critical velocity are

$$\begin{aligned} \omega &= \frac{\pi^2}{l^2} \sqrt{\frac{EI}{m+m_L}} \sqrt{1 - \frac{l^2}{\pi^2 EI} (m_L V^2 + PA_0)} \\ V_{\text{cr}_0} &= \sqrt{\frac{1}{m_L} \left(EI \frac{\pi^2}{l^2} - PA_0 \right)} \end{aligned}$$

From these equations, one may easily obtain formulas for frequency of vibration and critical velocity if internal pressure $P = 0$, or the velocity of the liquid $V = 0$.

14.6 HORIZONTAL PIPELINE UNDER A MOVING LIQUID AND INTERNAL PRESSURE

Consider a horizontal pipeline under self-weight, moving liquid and internal pressure P ; the velocity of the liquid, V , and the stiffness of the beam, EI , are constant (Fig. 14.8). The initial deflection is taken into account. The quasi-static regime is discussed.

Distributed load on the beam

$$w = w_0 - (m + m_L) \frac{\partial^2 y}{\partial t^2} - (m_L V^2 + PA_0) \frac{\partial^2 y}{\partial x^2} \quad (14.48)$$

where w_0 is the uniformly distributed force due to self-weight.

14.6.1 Static nonlinearity

The beam rests on two immovable supports (Fig. 14.9).

Total deflection of a beam

$$y(x, t) = y_1(x) + y_2(x, t) \quad (14.49)$$

where y_1 and y_2 are deflections that correspond to the quasi-static regime only and the process of vibration, respectively.

Differential equation of the beam under static nonlinearity

$$\frac{\partial^4 y}{\partial x^4} + b \frac{\partial^2 y}{\partial t^2} + \frac{\partial^2 y}{\partial x^2} \left(C^* - a \int_0^l \left(\frac{\partial y}{\partial x} \right)^2 dx \right) = \frac{w_0}{EI} \quad (14.50)$$

where

$$b = \frac{m + m_L}{EI}; \quad a = \frac{1}{2lr^2} = \frac{A}{2I}; \quad C^* = \frac{m_L V^2 + PA_0}{EI}$$

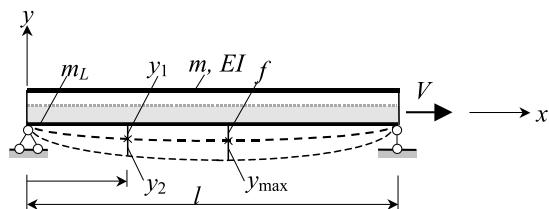

FIGURE 14.9. Pipeline under moving liquid. The initial deflection is taken into account.

Approximate equation for normal functions. Quasi-static regime

$$y_1'' + y_1'' \left[C^* - a \int_0^l (y')^2 dx \right] = \frac{w_0}{EI}$$

Dynamic regime

$$\frac{\partial^4 y_2}{\partial x^4} + b \frac{\partial^2 y_2}{\partial t^2} - 2a \frac{\partial^2 y_1}{\partial x^2} \int_0^l \frac{\partial y_1}{\partial x} \frac{\partial y_2}{\partial x} dx + \frac{\partial^2 y_2}{\partial x^2} \left(C^* - a \int_0^l \left(\frac{\partial y_1}{\partial x} \right)^2 + \left(\frac{\partial y_2}{\partial x} \right)^2 dx \right) = 0$$

If $y_2(x, t) = X(x) \cos \omega(t)$, then the equation for the normal function, X , becomes

$$X''' - b\omega^2 X + X'' \left\{ C^* - a \left[\int_0^l (y'_1)^2 dx + \frac{3}{4} \int_0^l (X')^2 dx \right] \right\} - 2y_1'' a \int_0^l y'_1 X' dx = 0$$

The deflection of the beam in the quasi-static regime is

$$y_1(x) = f \sin \frac{\pi x}{l}$$

where the maximum deflection of the linear problem is

$$f = \frac{4w_0 l^4}{\pi^5 EI} \frac{1}{1 - \frac{l^2}{\pi^2 EI} (m_L V^2 + PA_0)}$$

Normal function $X(x) = y_{\max} \sin \frac{\pi x}{l}$.

Frequency of vibration

$$\omega = \frac{\pi^2}{l^2} \sqrt{\frac{EI}{m + m_L}} \sqrt{1 + \frac{l^2}{\pi^2} \left[\frac{3}{4} \pi^2 \left(\frac{f + y_{\max}}{2lr} \right)^2 - \frac{1}{EI} (m_L V^2 + PA_0) \right]} \quad (14.51)$$

Deflection f of the beam in the quasi-static regime increases the frequency of vibration. The equation for nonlinear critical velocity

$$1 + \frac{l^2}{\pi^2} \left[3 \left(\frac{w_0 l^3}{\pi^4 r EI} \right)^2 \frac{1}{S^2} - \frac{m_L V_{cr}^2 + PA_0}{EI} \right] = 0$$

where

$$S = 1 - \frac{l^2}{\pi^2 EI} (m_L V_{cr}^2 + PA_0)$$

14.6.2 Physical nonlinearity

If the material of a simply-supported beam has a hardening characteristic of nonlinearity (14.9), then the frequency of free vibration may be calculated as follows

$$\omega = \frac{\pi^2}{l^2} \sqrt{\frac{EI_2}{m+m_L}} \sqrt{1 + \frac{l^2}{\pi^2} \left[\frac{27\beta I_4 \pi^6}{16 EI_2 l^6} (f+y_{\max})^2 - \frac{1}{EI_2} (m_L V^2 + PA_0) \right]}$$

The equation for critical velocity

$$1 + \frac{l^2}{\pi^2} \left[\frac{3\beta I_4}{EI_2} \left(\frac{3w_0 l}{\pi^2 EI_2} \right)^2 \frac{1}{S^2} - \frac{m_L V_{\text{cr}}^2 + PA_0}{EI_2} \right] = 0$$

where

$$S = 1 - \frac{l^2}{\pi^2 EI_2} (m_L V_{\text{cr}}^2 + PA_0)$$

Note

1. Hardening nonlinearity ($\beta > 0$): the critical velocity for a physically nonlinear problem is more than for a linear one, $V_{\text{cr.}} > V_{\text{cr.lin.}}$.
2. Softening nonlinearity ($\beta < 0$): the critical velocity for a physically nonlinear problem is less than for a linear one, $V_{\text{cr.}} < V_{\text{cr.lin.}}$.

CHAPTER 15

ARCHES

Chapter 15 considers the vibration of arches. Fundamental relationships for uniform and non-uniform arches are presented – they are the differential equations of vibrations, strain and kinetic energy, as well as the governing functional. Eigenvalues for arches with different equations of the neutral line, different boundary conditions, uniform, continuously and discontinuously varying cross-sections are presented.

NOTATION

A	Cross-sectional area
E, ρ	Young's modulus and the density of the material of the arch
EI	Bending stiffness
f, l	Rise and span of an arch
I_0	Second moment of inertia with respect to the neutral line of the cross-sectional area
m	Mass per unit length of an arch
M, N, Q	Bending moment, normal force and shear force
n	Integer number
r	Radius of gyration, $r^2 A = I$
$R(\alpha)$	Radius of curvature
t	Time
U, T	Potential and kinetic energy
v	Tangential displacement of an arch
$V_0(\alpha), W_0(\alpha)$	Tangential and rotational amplitude displacement
w	Radial displacement of an arch
x	Spatial coordinates
x, y, z	Cartesian coordinates
α	Slope
β_0	Angle of opening
ψ	Angle of rotation of the cross-section
ω	Natural frequency

15.1 FUNDAMENTAL RELATIONSHIPS

This section presents the geometric parameters for arches with various equations of the neutral line (i.e. different shapes of arches) as well as differential equations of vibrations of arches.

15.1.1 Equation of the neutral line in term of span l and arch rise h

Different shapes of arches and notations are presented in Fig. 15.1 (Bezukhov, 1969; Lee and Wilson, 1989).

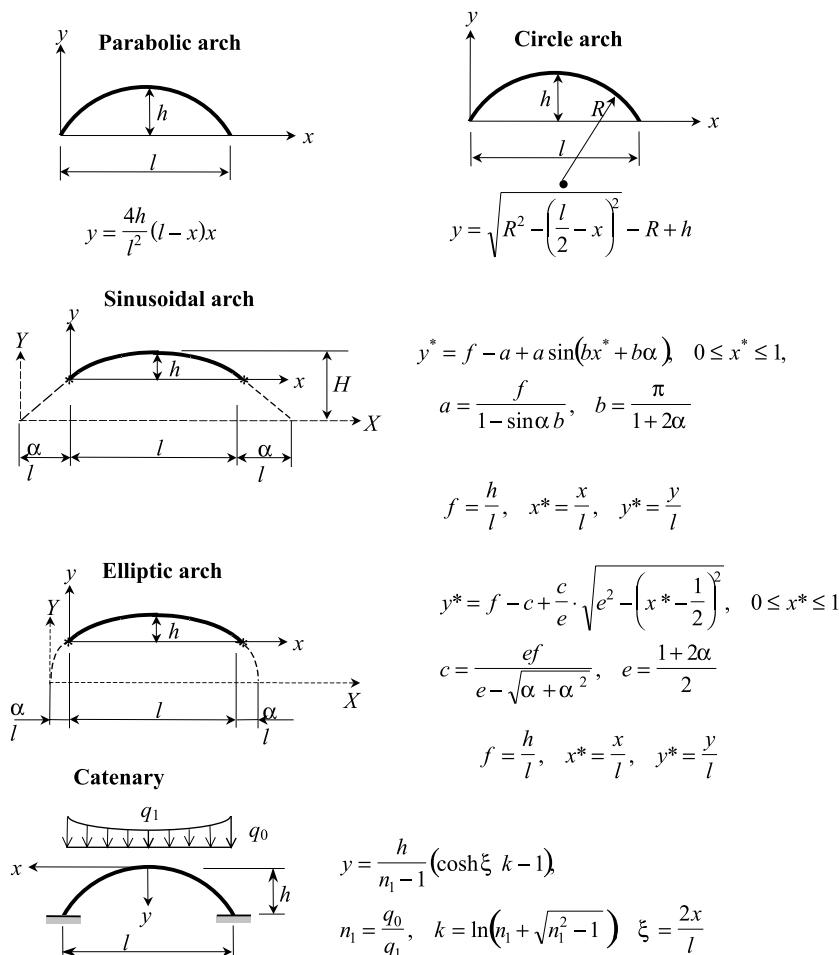

FIGURE 15.1. Types of arches and equations of the neutral line.

15.1.2 Equation of the neutral line in terms of radius of curvature R_0 and slope α

Figure 15.2 presents arch notation in the polar coordinate system. The radius of curvature is given by the functional relation (Romanelli and Laura, 1972; Laura *et al.*, 1988; Rossi *et al.*, 1989):

$$R(\alpha) = R_0 \cos^n \alpha \quad (15.1)$$

where R_0 is the radius of curvature at $\alpha = 0$ and n is an integer specified for a typical line (Table 15.1).

For an elliptic arch, the equations of neutral line in standard form and the radius of curvature are as follows:

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1 \quad R = a^2 b^2 \left(\frac{1 + \tan^2 \alpha}{a^2 \tan^2 \alpha + b^2} \right)^{3/2}$$

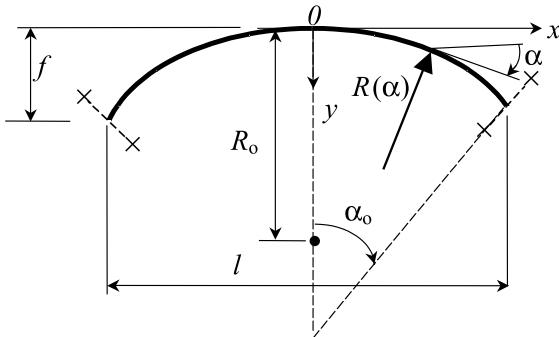

FIGURE 15.2. Arch geometry. Boundary conditions are not shown.

TABLE 15.1. Geometry relationships of the arches with different equations of the neutral line

Curve	Parameter n	Equation of the neutral line	Parameters	
			l/R_0	f/R_0
Parabola	-3	$y = x^2/2R_0$	$2 \tan \alpha_0$	$\frac{1}{2} \tan^2 \alpha_0$
Catenary	-2	$y = R_0 (\cosh x/R_0 - 1)$	$2 \operatorname{arc sinh} \tan \alpha_0$	$1/\cos \alpha_0 - 1$
Spiral	-1	$y = -R_0 \ln \cos x/R_0$	$2\alpha_0$	$-\ln \cos \alpha_0$
Circle	0	$y = R_0 - \sqrt{R_0^2 - x^2}$	$2 \sin \alpha_0$	$1 - \cos \alpha_0$
Cycloid	1	$x = \frac{R_0}{4} \arccos \left(\frac{4y}{R_0} - 1 \right) \pm \sqrt{y \left(\frac{R_0}{2} - y \right)} - \frac{R_0 \pi}{4}$	$\alpha_0 + \frac{1}{2} \sin 2\alpha_0$	$1 - \cos 2\alpha_0$

The instantaneous radius of curvature, R , of an axis of any type of arch is expressed in terms of polar coordinates ρ and α as follows

$$R = \frac{[\rho^2 + (\rho')^2]^{3/2}}{\rho^2 - \rho\rho'' + 2(\rho')^2}, \rho' = \frac{d\rho}{dx}, \rho'' = \frac{d^2\rho}{dx^2}$$

15.1.3 Differential equations of in-plane vibrations of arches

This section considers the fundamental relationship for an arch of non-uniform cross-section with a variable radius of curvature.

The geometry of a uniform, symmetric arch with a variable radius of curvature $R(\alpha)$ is defined in Fig. 15.3. Its span length, rise, shape of middle surface, and inclination with the x -axis are l , h , $y(x)$ and α , respectively. The positive radial, w , and tangential, v , displacements, positive rotation ψ of cross-section, as well as all internal forces – axial forces N , bending moments M , shear forces V , and rotary inertia couple T – are shown (Rzhanitsun, 1982; Lee and Wilson, 1989; Borg and Gennaro, 1959 convention is used). Radial and tangential displacement, and angle of rotation, are related by the following formulas

$$w = \frac{\partial v}{\partial \alpha}, \psi = \frac{1}{R}(w' - v), \text{ where } () = \frac{d}{d\alpha} \quad (15.2)$$

Assumptions (Navier's hypothesis)

- (1) A plane section before bending remains plane after bending.
- (2) The cross-section of an arch is symmetric with respect to the loading plane.
- (3) Hook's law applies.
- (4) Deformations are small enough so that the values of the stresses and moments are not substantially affected by these deformations.

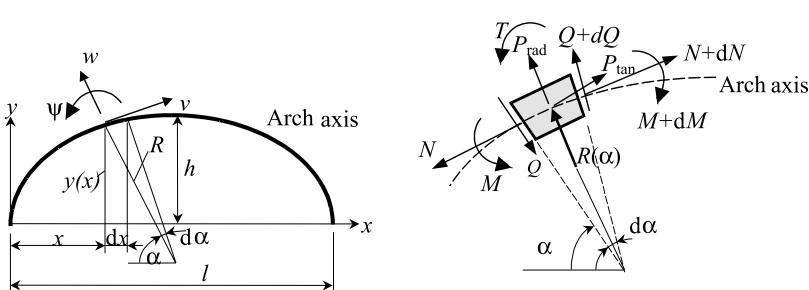

FIGURE 15.3. Arch geometry and loads on the arch element.

With the specified assumptions, the fundamental equations for the ‘dynamic equilibrium’ of an element are

$$\begin{aligned}\frac{dN}{dx} + Q + RP_{\tan} &= 0 \\ \frac{dQ}{dx} - N + RP_{\rad} &= 0 \\ \frac{dM}{dx} - RQ - RT &= 0\end{aligned}\tag{15.3}$$

The inertial forces and couple are

$$\begin{aligned}P_{\rad} &= m\omega^2 w \\ P_{\tan} &= m\omega^2 v \\ T &= m\omega^2 r^2 \psi\end{aligned}\tag{15.4}$$

where m = mass per unit length

r = radius of gyration of a cross-section

ω = frequency of vibration

Internal forces in terms of tangential and radial displacements, and radius of curvature are

$$\begin{aligned}N &= \frac{EA}{R} \left[v' + w + \frac{r^2}{R^2} (w'' + w) \right] \\ M &= -EA \frac{r^2}{R^2} (w'' + w) \\ Q &= \frac{1}{R} \cdot \frac{dM}{dx} - ST = -EA r^2 \left[\frac{1}{R^3} (w''' + w') - 2 \frac{R'}{R^4} (w'' + w) \right] - S \frac{m\omega^2 r^2}{R} (w' - v)\end{aligned}\tag{15.5}$$

where S is a switch function. The switch function $S = 1$ if the rotatory inertia couple T is included, and $S = 0$ if T is excluded.

Differential equations for N , V and M are as follows

$$\begin{aligned}\frac{dN}{dx} &= EA \left[\frac{1}{R} (v'' + w') + \frac{r^2}{R^3} (w''' + w') - \frac{R'}{R^2} (v' + w) - \frac{3r^2 R'}{R^4} (w'' + w) \right] \\ \frac{dM}{dx} &= -EA r^2 \left[\frac{1}{R^2} (w''' + w') - \frac{2R'}{R^3} (w'' + w) \right] \\ \frac{dQ}{dx} &= -EA r^2 \left[\frac{1}{R^3} (w'''' + w') - \frac{5R'}{R^4} (w''' + w') + 2 \left(\frac{4R'^2}{R^5} - \frac{R''}{R^4} \right) \cdot (w'' + w) \right] \\ &\quad - S m\omega^2 r^2 \left[\frac{1}{R} (w'' - v') - \frac{R'}{R^2} (w' - v) \right]\end{aligned}\tag{15.6}$$

Special case. Consider arches with constant curvature ($R = R_0 = \text{constant}$). In this case, the in-plane vibration of a thin curve element is described by the following differential equations, which are obtained from (15.3) ($ds = Rd\alpha$):

$$\begin{aligned}\frac{dN}{ds} + \frac{Q}{R} + P_{\tan} &= 0 \\ \frac{dQ}{ds} - \frac{N}{R} + P_{\rad} &= 0 \\ \frac{dM}{ds} - Q - T &= 0\end{aligned}$$

If $R = \infty$, then the equations break down into two independent equations, which describe the longitudinal and transverse vibrations of a beam.

Strain and kinetic energy of an arch. Potential energy U and kinetic energy T of a non-uniform arch may be presented in the following forms.

Form 1. This form uses a curvilinear coordinate s along the arch

$$U = U_1 + U_2 \quad (15.7)$$

$$U_1 = \frac{1}{2} \int_0^l EI \left[\frac{\partial^2 w}{\partial s^2} + \frac{\partial}{\partial s} \left(\frac{v}{R} \right) \right]^2 ds \quad (15.8)$$

$$U_2 = \frac{1}{2} \int_0^l EA \left(\frac{\partial v}{\partial s} - \frac{w}{R} \right)^2 ds \quad (15.9)$$

$$T = \frac{1}{2} \int_0^l \rho A \left[\left(\frac{\partial v}{\partial t} \right)^2 + \left(\frac{\partial w}{\partial t} \right)^2 \right] ds \quad (15.10)$$

Form 2. This form uses angular coordinate α : $ds = Rd\alpha$

$$U_1 = \frac{1}{2} \int_0^\alpha EI(\alpha) \left(\frac{\partial^2 w}{\partial \alpha^2} - \frac{1}{R(\alpha)} \frac{\partial R}{\partial \alpha} \frac{\partial w}{\partial \alpha} + w - \frac{1}{R(\alpha)} \frac{\partial R}{\partial \alpha} v \right)^2 d\alpha \quad (15.11)$$

$$T = \frac{1}{2} \int_0^\alpha \rho A \left[\left(\frac{\partial v}{\partial t} \right)^2 + \left(\frac{\partial w}{\partial t} \right)^2 \right] R d\alpha \quad (15.12)$$

Expression (15.11) may be presented in a form that contains only tangential displacement

$$U_1 = \frac{1}{2} \int_0^\alpha EI(\alpha) \left(\frac{\partial^3 v}{\partial \alpha^3} + \frac{\partial v}{\partial \alpha} - \frac{1}{R} \frac{\partial R}{\partial \alpha} \left(\frac{\partial^2 v}{\partial \alpha^2} + v \right) \right)^2 d\alpha \quad (15.13)$$

Governing functional. Tangential and radial displacements are

$$\begin{aligned}v(a, t) &= V_0(a) \exp(i\omega t) \\ w(a, t) &= W_0(a) \exp(i\omega t)\end{aligned} \quad (15.14)$$

where V_0 and W_0 are normal modes that are related by the formula $W_0 = dV_0/d\alpha$.

The maximum kinetic energy of lumped mass M_0 , which is attached at $\alpha = \alpha_0$, is determined by the formula

$$T = \frac{1}{2} M_0 \omega^2 (V_0^2 + W_0^2) \Big|_{\alpha=\alpha_0} \quad (15.15)$$

where ω is the frequency of vibration.

Ritz's classical method requires that the functional

$$J[V_0] = U_{\max} - T_{\max} \quad (15.16)$$

be a minimum. This leads to the governing functional

$$\begin{aligned} J[V_0] = & \frac{E}{2} \int_{(x)} \frac{I(x)}{R^3(x)} \left[V_0''' + V_0' - \frac{R'(x)}{R(x)} (V_0'' + V_0) \right]^2 dx \\ & - \frac{\rho \omega^2}{2} \int_{(x)} A(x) R(x) (V_0'^2 + V_0^2) dx - \frac{M}{2} \omega^2 (V_0'^2 + V_0^2) \Big|_{x=0} \end{aligned} \quad (15.17)$$

where V_0 = tangential displacement amplitude

$R(x)$ = radius of curvature at any arbitrary point

$A(x)$ = cross-sectional area

$I(x)$ = second moment of inertia of cross-sectional area

The last term in the equation (15.17) takes into account a lumped mass M_0 at $\alpha = \alpha_0$.

15.2 ELASTIC CLAMPED UNIFORM CIRCULAR ARCHES

This section provides eigenvalues for uniform circular arches with elastic supports.

A circular arch with constant cross-section and elastic supports is shown in Fig. 15.4. Here m = constant distributed mass

R = radius of the arch

2α = angle of opening

Assumptions:

- (1) Axis of arch is inextensible.
- (2) Shear effects and rotary inertia can be neglected.
- (3) Cross-section is small in comparison with the radius of an arch.

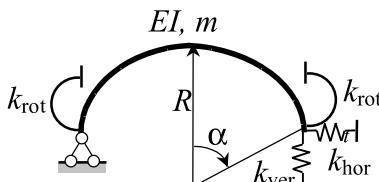

FIGURE 15.4. Clamped uniform circular arch with various types of elastic supports.

The non-dimensional rotational stiffness parameter and the vertical and horizontal stiffnesses are as follows

$$\beta_r = \frac{k_{\text{rot}}R}{EI}$$

$$\beta_v = \frac{k_{\text{vert}}R^3}{EI}$$

$$\beta_h = \frac{k_{\text{hor}}R^3}{EI}$$

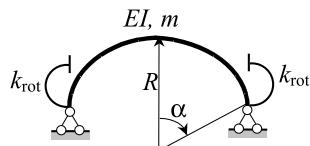

The mathematical model, numerical procedure and results (Table 15.2) are obtained and discussed by De Rosa (1991). The square of frequency vibration is

$$\omega^2 = \frac{\lambda EI}{mR^4} \quad (15.18)$$

Table 15.2(a)–(e) present the frequency parameter λ for different types of elastic supports.

Type 1. Circle. ($\beta_{\text{vert}} = \infty$, $\beta_{\text{hor}} = \infty$)

$$\beta_r = \frac{k_{\text{rot}}R}{EI}$$

Type 2. Circle. ($\beta_{\text{rot}} = \infty$, $\beta_{\text{vert}} = \infty$)

$$\beta_h = \frac{k_{\text{hor}}R^3}{EI}$$

90	Upper	3.14	1.66	0.80	0.57	0.26
	Lower	3.09	1.64	0.80	0.57	0.26

The parameter of the flexibility, ϕ , of the elastic support defines the angle of rotation in accordance with the relation $\theta = \phi M$. The fundamental frequency of vibration may be calculated by the formula

$$\omega = \frac{\lambda_1}{(R_0 \alpha_0)^2} \sqrt{\frac{EI_0}{\rho A_0}} \quad (15.19)$$

Upper and lower bounds for the fundamental frequency coefficient, λ_1 , for different angles α_0 ° and dimensionless parameter, $\phi^* = \frac{\phi EI_0}{R_0 \alpha_0}$ (where α_0 is in radians), are presented in Table 15.3 (Laura *et al.*, 1987).

15.3 TWO-HINGED UNIFORM ARCHES

15.3.1 Circular arch. In-plane vibrations

A two-hinged circular uniform arch with central angle $2\alpha_0$ is presented in Fig. 15.5(a).

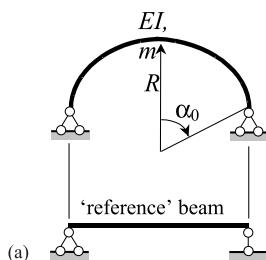

FIGURE 15.5. (a) Two-hinged uniform circular arch and end-supported 'reference' beam.

The frequency of vibration of an arch is calculated by the formula

$$\omega = \frac{\beta(\beta^2 - 1)}{\sqrt{\lambda(\beta^2 + 3)}} \quad (15.20)$$

where $\lambda = \frac{mR^4}{EI}$, $\beta = \frac{\pi}{\alpha_0}$.

The frequency of vibration, ω , of an arch in terms of the frequency of vibration, ω_0 , of the simply supported ‘reference’ beam (Bezukhov *et al.*, 1969) is

$$\omega = \omega_0 \sqrt{\frac{1 - n^2}{1 + 3n^2}}, n = \frac{\alpha_0}{\pi} \quad (15.21)$$

The frequencies of vibration, which correspond to fundamental (antisymmetric) and second (symmetric) modes, may be calculated as follows

$$\omega = \frac{\lambda}{4R^2\alpha_0^2} \sqrt{\frac{EI}{\rho A}} \quad (15.22)$$

where α_0 is in radians.

The corresponding frequency coefficients λ_1 and λ_2 are presented in Table 15.4 (Gutierrez *et al.*, 1989).

TABLE 15.4. Two-hinged uniform circular arch: frequency parameters for first and second modes of vibration

$2\alpha_0$ (degrees)	Antisymmetric mode λ_1	Symmetric mode λ_2
10	39.40	84.25
20	39.18	84.09
30	38.80	83.81
40	38.29	83.43

The fundamental frequency of vibration corresponds to the first antisymmetric mode of vibration. Frequency coefficients λ_1 and λ_2 , which are obtained using different numerical methods, are compared in Gutierrez *et al.* (1989).

15.3.2 Circular arch with constant radial load. Vibration in the plane

A circular arch of uniform cross-section under constant hydrostatic pressure X is presented in Fig. 15.5(b).

The fundamental frequency of vibration of an arch is

$$\omega = \beta \sqrt{\frac{(\beta^2 - 1)(\beta^2 - 1 - c^2)}{\lambda(\beta^2 + 3)}} \quad (15.23)$$

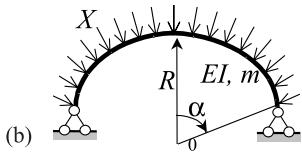

FIGURE 15.5 (b) Two-hinged uniform circular arch under constant hydrostatic pressure.

where the non-dimensional parameters are

$$\lambda = \frac{mR^4}{EI}, c^2 = \frac{XR^3}{EI}, \beta = \frac{\pi}{\alpha_0}$$

The inertial force due to the angle of rotation is neglected (Bezukhov *et al.*, 1969)

Critical pressure

$$X \leq \frac{EI}{R^3}(\beta^2 - 1)$$

Special case. Hydrostatic pressure $X = 0$. In this case expression (15.23) transforms to expression (15.20).

15.3.3 Shallow parabolic arch. In-plane vibration

A shallow parabolic arch carrying a uniformly distributed load q is presented in Fig. 15.6.

The fundamental frequency of vibration of an arch

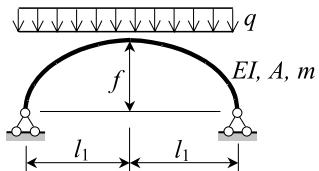

FIGURE 15.6. Shallow parabolic arch carrying a uniformly distributed load.

$$\omega^2 = \frac{\pi^4(1 - 0.5653k^2)}{1 + 4.1277k^2 + 1.6910k^4} \frac{EIg}{ql_1^4} \quad (15.24)$$

where $k = f/l_1$.

This expression has been obtained by the Ritz method and yields good results if $f \leq 0.3l$, $l = 2l_1$ (Morgaevsky, 1940; Bezukhov *et al.*, 1969).

15.3.4 Non-circular arches

Figure 15.7 shows a design diagram of a symmetric arch with different equations of the neutral line. Geometric relationships for different curves are presented in Table 15.1.

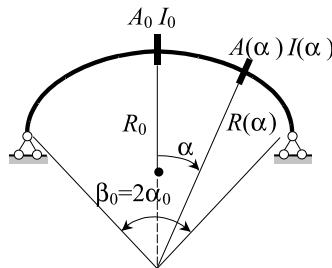

FIGURE 15.7. Two-hinged non-circular arch.

The fundamental frequency of vibration for arches corresponds to the first antisymmetric mode of vibration.

The frequency of vibration of uniform symmetric arches with different equations of the neutral line may be presented by the formula

$$\omega = \frac{\lambda}{(R_0 \beta_0)^2} \sqrt{\frac{EI}{\rho A_0}} \quad (15.25)$$

where $\beta_0 = 2\alpha_0$ = the angle of opening of arch

R_0 = radius at the axis of symmetry, which corresponds to $\alpha = 0$

A_0 = cross-section area at $\alpha = 0$

I_0 = second moment of inertia of the cross-section area at $\alpha = 0$

TABLE 15.5. Two-hinged uniform arches with different shapes of neutral line: first and second frequency parameters

Arch's shape	β_0 (degrees)	Antisymmetric mode λ_1	Symmetric mode λ_2

	30	39.70	85.48
	40	39.88	86.46

The first and second frequency parameters, λ_1 and λ_2 , as a function of β_0 for different arch shapes, are tabulated in Table 15.5. These parameters correspond to fundamental (antisymmetric) and lowest symmetric modes, respectively. For their determination the governing functional (15.11a) has been used (Gutierrez *et al.*, 1989).

15.3.5 Circular arch. Out-of-plane vibration of arch

The $a-a$ axis of hinge supports, is horizontal and located in the plane of the arch (Fig. 15.8). The bending stiffness EI and mass m per unit length are constant.

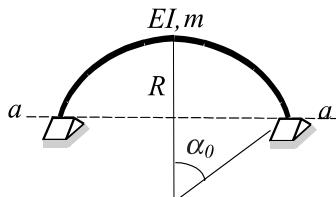

FIGURE 15.8. Design diagram of uniform circular arch for out-of-plane vibration.

The antisymmetric frequency of vibration is determined by the following formula (Bezukhov *et al.*, 1969)

$$\omega = \frac{k\pi(x_0^2 - k^2\pi^2)}{\alpha_0^2 R^2} \sqrt{\frac{EI}{m(k^2\pi^2 + \alpha_0^2\chi)}} \quad (15.26)$$

The symmetric k th frequency of vibration

$$\omega_k = \frac{(2k-1)\pi[4x_0^2 - (2k-1)^2\pi^2]}{4x_0^2 R^2} \sqrt{\frac{EI}{m(2k-1)^2\pi^2 + 4x_0^2\chi}} \quad (15.27)$$

where $\chi = \frac{EI}{GJ}$, I and J are the axial and polar moments of inertia of the cross-sectional area; and $k = 1, 2, 3, \dots$,

15.4 HINGELESS UNIFORM ARCHES

15.4.1 Circular arch

The natural frequency of vibration of a circular uniform arch with clamped ends may be calculated by the formula

$$\omega = \frac{\lambda}{(R\beta_0)^2} \sqrt{\frac{EI}{\rho A}}$$

where β_0 is the angle of opening (radians).

Coefficients λ_1 and λ_2 are listed in Table 15.6 (Gutierrez *et al.*, 1989). Comparisons of frequency coefficients, which are obtained by different numerical methods, can be found in Gutierrez *et al.* (1989).

TABLE 15.6. Hingeless uniform circular arch: frequency parameters for first and second mode of vibration

β_0 (degrees)	Antisymmetric mode λ_1	Symmetric mode λ_2
10	61.59	110.94
20	61.35	110.78
30	60.96	110.51
40	60.42	110.13

15.4.2 Circular arch with constant radial load

The uniform circular arch with clamped ends carrying a constant radial load is shown in Fig. 15.9.

The differential equation of in-plane vibration is discussed in Section 15.1.3. The

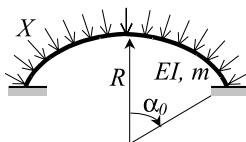

FIGURE 15.9. Clamped circular arch with radial load.

fundamental frequency of vibration is obtained by the integration of the differential equation (Bezukhov *et al.*, 1969)

$$\omega = \frac{3}{4} \beta \sqrt{\frac{41\beta^4 - 20\beta^2(2 + c^2) + 16(1 + c^2)}{9\beta^2 + 20}} \frac{1}{R^2} \sqrt{\frac{EI}{m}} \quad (15.28)$$

$$\text{where } \beta = \frac{180^\circ}{\alpha_0}, \quad c^2 = \frac{XR^3}{EI}$$

Vibration is unstable if $41\beta^4 - 20\beta^2(2 + c^2) + 16(1 + c^2) < 0$.

15.4.3 Non-circular arches

Notations for hingeless arches with different shapes are presented in Fig. 15.10.

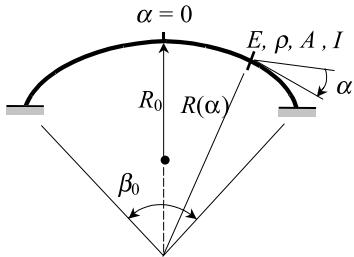

FIGURE 15.10. Hingeless arches with different shapes.

The frequency of vibration of uniform symmetric arches with different shapes may be calculated by the formula

$$\omega = \frac{\lambda}{(R_0 \beta_0)^2} \sqrt{\frac{EI}{\rho A}}$$

where the central angle of the arch is β_0 (in radians); the radius of curvature R_0 is shown at the axis of symmetry; the cross-section area, A , and the second moment of inertia, I , are constant (Fig. 15.10).

The governing functional is presented by expression (15.17). First and second frequency parameters λ_1 and λ_2 are listed in Table 15.7. These parameters correspond

to fundamental (antisymmetric) and lowest symmetric modes, respectively. For their determination, a finite element method has been used (Gutierrez *et al.*, 1989). This article contains also frequency coefficients that are obtained by using polynomial approximations and the Ritz method.)

15.5 CANTILEVERED UNIFORM CIRCULAR ARCH WITH A TIP MASS

The uniform circular arch with a clamped support at one end and a tip mass at the other is presented in Fig. 15.11. Parameters A , R and EI are constant.

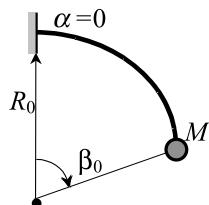

FIGURE 15.11. Cantilevered uniform circular arch with a tip mass.

The fundamental frequency of the in-plane transverse vibration in the case of a constant cross-section area, may be calculated by the formula

$$\omega = \frac{\lambda_1}{(R\beta_0)^2} \sqrt{\frac{EI}{\rho A}}$$

Upper and lower bounds for the fundamental frequency coefficient, λ_1 , in terms of the non-dimensional parameter $M^* = \frac{M}{\rho AR\beta_0}$ and angle β_0 are listed in Table 15.8.

Upper bounds are determined using the Rayleigh–Ritz method (the governing functional is presented by formula (15.17) for the case when $R = \text{constant}$); lower bounds are obtained using the Dunkerley method (Laura *et al.*, 1987).

15.6 CANTILEVERED NON-CIRCULAR ARCHES WITH A TIP MASS

Figure 15.12 presents a non-circular arch of non-uniform cross-section, rigidly clamped at one end and carrying a concentrated mass at the other. The tangential displacement at any point of an arch is $v = V_0(\alpha) \exp(i\omega t)$.

The governing functional is presented by the formula

$$J[V_0] = \frac{E}{2} \int_0^{\beta_0} \frac{I(\alpha)}{R^3(\alpha)} \left[V_0''' + V_0' - \frac{R'(\alpha)}{R(\alpha)}(V_0'' + V_0) \right]^2 d\alpha - \frac{\rho\omega^2}{2} \int_0^{\beta_0} A(\alpha)R(\alpha) \cdot (V_0'^2 + V_0^2) d\alpha - \frac{M}{2} \omega^2 (V_0'^2 + V_0^2) \Big|_{\alpha=0}$$

where V_0 is the tangential displacement amplitude, $V' = dV/d\alpha$.

15.6.1 Arch of uniform cross-section

A non-circular arch of uniform cross-section, rigidly clamped at one end and carrying a concentrated mass at the other, is presented in Fig. 15.12. The fundamental frequency of

the in-plane transverse vibration of elastic arches is

$$\omega_1 = \frac{\lambda_1}{(R_0\beta_0)^2} \sqrt{\frac{EI}{\rho A}}$$

where ρ = the mass density of the arch material

β_0 = central angle (radians)

R_0 = radius of an arch at $\alpha = 0$

The fundamental frequency coefficients, λ_1 , in terms of the non-dimensional mass $M^* = \frac{M}{\rho A R_0 \beta_0}$ and angle β_0 for arches with different shapes are listed in Table 15.9. The Rayleigh optimization method has been used to obtain the results (Rossi *et al.*, 1989).

TABLE 15.9. Cantilevered uniform non-circular arch with a tip mass: fundamental frequency parameter λ

The above mentioned reference contains a comparison of the fundamental frequency coefficients λ_1 , which are obtained using different numerical methods.

15.6.2 Arch with a discontinuously varying cross-section

A non-circular arch of non-uniform cross section, rigidly clamped at one end and carrying a concentrated mass at the other is presented in Fig. 15.13.

Expressions for tangential and radial displacements $v(\alpha, t)$, $w(\alpha, t)$ and the corresponding governing functional are presented in Section 15.1.3.

The fundamental frequency in-plane transverse vibration is

$$\omega_1 = \frac{\lambda_1}{(R_0\beta_0)^2} \sqrt{\frac{EI_0}{\rho A_0}}$$

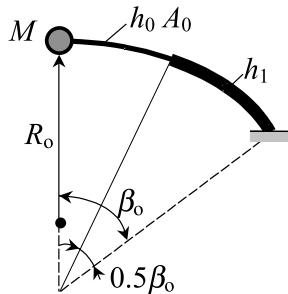

FIGURE 15.13. Cantilevered non-circular arch of discontinuously varying cross-section.

where β_0 (radians) is the central angle. The frequency coefficient, λ_1 , for different non-dimensional mass, $M^* = \frac{M}{\rho A_0 R_0 \beta_0}$, geometry ratio, h_1/h_0 , and various equations of the neutral line of the arches are presented in Tables 15.10(a) and (b). The finite element method has been used to obtain numerical results (Rossi *et al.*, 1989). This article contains results that are obtained using a polynomial approximation (a one-term solution and a three-term solution) and an optimization approach.)

Note: if parameter M^* is fixed while h^* is varying, then the fundamental frequency coefficient λ_1 for the cycloid arch as a function of parameter $h^* = h_1/h_0$ is presented in Table 15.11 (for $M^* = 1.0$). The finite element method has been used (Rossi *et al.*, 1989).

15.6.3 Arch of continuously varying cross-section

An arch of continuously varying cross-section, rigidly clamped at one end and carrying a concentrated mass M at the other, is presented in Fig. 15.14.

The height of the cross-section for any angle α is determined by the following formula

$$h(\alpha) = h_0 \left(1 + \eta \frac{\alpha}{\beta_0} \right)$$

where h_0 is the height of cross-section at $\alpha = 0$; and the η parameter, which represents the increase of the height of the cross-section at given α , can be any number.

The fundamental frequency of vibration of an elastic arch with central angle β_0 (rad) may be calculated by the formula

$$\omega_1 = \frac{\lambda_1}{(R_0 \beta_0)^2} \sqrt{\frac{EI_0}{\rho A_0}}$$

Frequency coefficients, λ , for various equations of the neutral line, opening angle, β° , parameter η and non-dimensional mass, M^* , are presented in Tables 15.12(a) and (b).

These results have been obtained by the finite element method; 12 prismatic beam elements have been used (Rossi *et al.*, 1989). This article contains results that are obtained using the Rayleigh optimization method.

Note: The varying cross-section for symmetric arches may be presented in the analytical form by the following expression (Darkov, 1989)

$$I_x = \frac{I_c}{\left[1 - (1-n) \frac{x}{l_1} \right] \cos \varphi_x}$$

where x = abscissa of any point on a neutral line, referred to the coordinate origin which is located at a centroid of a crown section

I_c = second moment of inertia of a crown section

TABLE 15.12. (b) Cantilevered non-circular arches of discontinuously varying cross-section with a tip mass: Fundamental frequency parameter λ for $\eta = 0.4$

	40	6.04	4.43	3.65	3.18	2.85	2.60

I_x = second moment of inertia of a cross-section area, which is located at a distance x from the coordinate origin

φ_x = angle between the tangent to the neutral line of the arch and the horizontal
 l_1 = one half of the arch span

The value of parameter n is given by formula

$$n = \frac{I_c}{I_0 \cos \varphi_0}$$

where I_0 , φ_0 correspond to the cross-section at the support.

15.7 ARCHES OF DISCONTINUOUSLY VARYING CROSS-SECTION

This section is devoted to the in-plane vibration of non-circular symmetric and non-symmetric arches of non-uniform cross-section with different boundary conditions. Figure 15.15 presents the notation of a non-circular arch of non-uniform cross-section.

The relationships $R(x)$ for different types of arch geometry are presented in Table 15.1. The mathematical model and governing functional are presented in Section 15.1.3. Numerical results for different arch shapes and boundary conditions, and types of discontinuously varying cross-sections, are presented in Tables 15.13–15.19 (Gutierrez *et al.*, 1989).

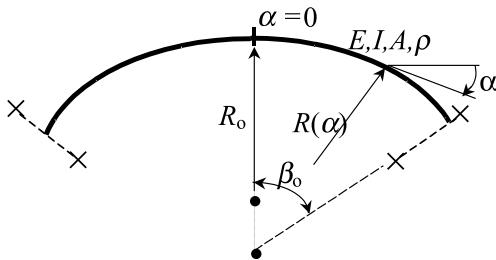

FIGURE 15.15. Arch geometry (boundary conditions are not shown).

15.7.1 Pinned-pinned arches

Two types of symmetric pinned-pinned arches of discontinuously varying cross-section are presented in Fig. 15.16.

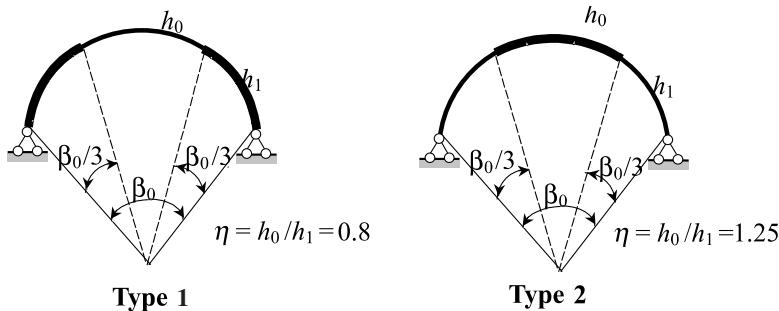

FIGURE 15.16. Pinned-pinned arches of discontinuously varying cross section.

The frequency of an in-plane vibration of an elastic arch for different arch shapes is

$$\omega = \frac{\lambda}{(R_0 \beta_0)^2} \sqrt{\frac{EI_0}{\rho A_0}}$$

where the parameter λ for the first and second modes of pinned-pinned arches for both types 1 and 2 are listed in Table 15.13. The finite element method has been used.

15.7.2 Clamped-clamped arches

Two types of symmetric clamped-clamped arches of discontinuously varying cross-section are presented in Fig. 15.17.

The frequency of in-plane vibration of elastic arches is

$$\omega = \frac{\lambda}{(R_0 \beta_0)^2} \sqrt{\frac{EI_0}{\rho A_0}}$$

15.7.3 Non-symmetric arches

Non-symmetric arches with different shapes of discontinuously varying cross-section are presented in Fig. 15.18.

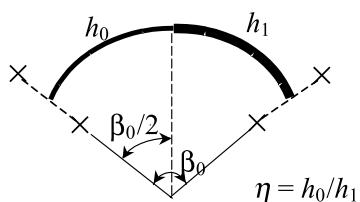

FIGURE 15.18. Non-symmetric arch (boundary conditions are not shown).

The fundamental frequency of in-plane vibration of elastic pinned and clamped arches is

$$\omega = \frac{\lambda}{(R_0\beta_0)^2} \sqrt{\frac{EI_0}{\rho A_0}}$$

The parameter λ for arches with different shapes is presented in Table 15.15. Polynomial approximations and the Ritz method are used.

The current angle $0 \leq \alpha \leq \beta$, $\beta = 0.5\beta_0$ and parameter η is any number. The fundamental and second frequency of in-plane vibration may be calculated by $\omega = \frac{\lambda}{(R_0\beta_0)^2} \sqrt{\frac{EI_0}{\rho A_0}}$. The frequency coefficients λ_1 and λ_2 , as a function of parameter η , central angle β_0 , various equations of the neutral line and different boundary conditions, are presented in Tables 15.16(a) and (b). The polynomial approximation and Ritz method have been applied (Gutierrez *et al.*, 1989).

15.7.5 Pinned-pinned symmetric arches

The design diagram is presented in Fig. 15.19(a). Fundamental and second frequency coefficients, λ_1 and λ_2 , as a function of the parameter η , central angle β_0 and various equations of the neutral line are presented in Table 15.16(a).

15.7.6 Clamped-clamped symmetric arch

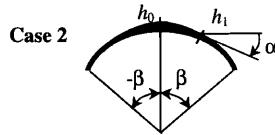

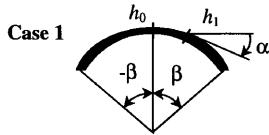

The design diagram is presented in Fig. 15.19(b). Fundamental and second frequency coefficients, λ_1 and λ_2 , as a function of the parameter η , central angle β_0 and various equations of the neutral line are presented in Table 15.16(b).

15.7.7 Arch structures of continuously varying cross-section

Different types of continuously varying cross-sections of elastic arch structures are presented in Fig. 15.20. Cases 1 and 2 present arches of symmetric varying cross-section, cases 3 and 4 present arches of non-symmetric varying cross-section.

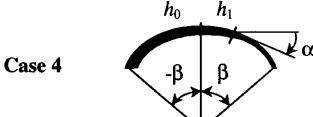

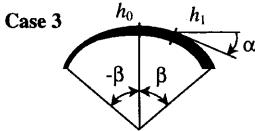

$$h_1 = h_0 \left(1 - \eta \frac{\alpha}{\beta}\right) - \beta \leq \alpha \leq 0$$

$$h_1 = 1 + \eta \frac{\alpha}{\beta} \quad 0 \leq \alpha \leq \beta$$

$$h_1 = h_0 \left(1 - \eta \frac{\alpha}{\beta}\right) - \beta \leq \alpha \leq 0$$

$$h_1 = 1 + \eta \frac{\alpha}{\beta} \quad 0 \leq \alpha \leq \beta$$

$$h_1 = h_0 \left(1 - \eta \frac{\alpha}{\beta}\right)$$

$$-\beta \leq \alpha \leq \beta$$

$$h_1 = h_0 \left(1 - \eta \frac{\alpha}{\beta}\right)$$

$$-\beta \leq \alpha \leq \beta$$

FIGURE 15.20. Different types of non-uniform cross-section of arch structures. Boundary conditions are not shown. Parameter η is any positive number.

The frequency of the in-plane vibration is

$$\omega = \frac{\lambda}{(R_0 \beta_0)^2} \sqrt{\frac{EI}{\rho A_0}}$$

where $\beta_0 = 2\beta$ is the angle of opening. Fundamental frequency parameters λ are predicted in Tables 15.17–15.19 (Gutierrez et al., 1989). Polynomial approximations and the Ritz method are used.

CHAPTER 16

FRAMES

This chapter deals with the vibration of frames. Eigenvalues for symmetric portal frames, symmetric multi-storey frames, viaducts, etc. are presented. A detailed example of the calculation of non-regular frames is discussed.

NOTATION

A	Cross-sectional area
B, C, S, D, E	Hohenemser–Prager functions
E	Young's modulus
EI	Bending stiffness
F, H, L, R	Frequency functions
g	Gravitational acceleration
I	Moment of inertia of a cross-sectional area
k, β	Dimensionless geometry parameters
l, h	Length of frame element
m	Mass per unit length
M	Concentrated mass
r_{ik}	Unit reaction
t	Time
x	Spatial coordinate
y	Transversal displacement
Z	Unknown of the slope-deflection method
α	Dimensionless mass ratio
λ	Frequency parameter, $\lambda^4 EI = ml^4 \omega^2$
ρ	Density of material
v	Eigenvector
ω	Natural frequency, $\omega^2 = \lambda^2 EI / ml^4$

16.1 SYMMETRIC PORTAL FRAMES

A portal symmetric frame with clamped supports is shown in Fig. 16.1. The distributed masses of elements per unit length are m_1 and m_2 . Additional distributed load, which is

carried by horizontal and vertical elements, are q_1 and q_2 , respectively (load q_2 is not shown).

The differential equation for each member is

$$EI \frac{\partial^4 y}{\partial x^4} + \rho_i A_i (1 + e_i) \frac{\partial^2 y}{\partial t^2} = 0, e_i = \frac{q_i}{g m_i}$$

where q_i/g is the mass per unit length of the distributed load, and m_i is the mass per unit length of a member itself.

For a symmetrical framed system, investigation of symmetrical and antisymmetrical vibrations, are considered separately.

16.1.1 Frame with clamped supports

A portal symmetric frame is presented in Fig. 16.1.

The dimensionless parameters, which are needed for calculation of the natural frequency of vibration are as follows:

$$\begin{aligned} k &= \frac{I_1 h}{I_2 l}, \beta = \frac{h}{l} \sqrt{\frac{A_2(1+e_2)I_1}{A_1(1+e_1)I_2}} \\ \alpha_1 &= \frac{A_1 \rho l (1+e_1)}{A_2 \rho h}, e_1 = \frac{q_1}{g \rho A_1} = \frac{q_1}{g m_1}, e_2 = \frac{q_2}{g \rho A_2} = \frac{q_2}{g m_2} \\ \lambda^4 &= \frac{\rho A_1 (1+e_1) l^4}{E I_1} \omega^2 \end{aligned}$$

The natural frequency of vibration may be calculated by the formula

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{E I_1}{\rho A_1 (1+e_1)}} \quad (16.1)$$

where λ are the roots of the frequency equation.

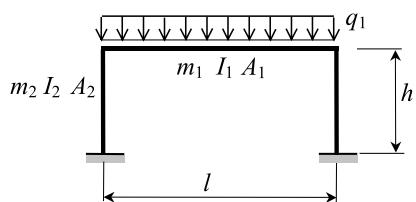

FIGURE 16.1. A portal symmetric frame with clamped supports.

Frequency equation. The frequency equation may be presented in terms of trigonometric–hyperbolic functions as follows (Filippov, 1970).

Symmetric vibration

$$\begin{aligned} \beta\lambda(\sin\beta\lambda \cdot \cosh\beta\lambda - \cos\beta\lambda \sinh\beta\lambda) &\left[\sin\frac{\lambda}{2} \cosh\frac{\lambda}{2} + \cos\frac{\lambda}{2} \sinh\frac{\lambda}{2} \right] \\ &+ 2\lambda k(1 - \cos\beta\lambda \cosh\beta\lambda) \cos\frac{\lambda}{2} \cosh\frac{\lambda}{2} = 0 \end{aligned} \quad (16.2)$$

Limiting case: if $h = 0$ or $I_2 = \infty$, then $k = 0$, $\beta = 0$ and the frequency of vibration is

$$\sin\frac{\lambda}{2} \cosh\frac{\lambda}{2} + \cos\frac{\lambda}{2} \sinh\frac{\lambda}{2} = 0$$

which corresponds to a clamped–guided beam with length of the span $0.5l$ (Table 5.4).

Antisymmetric vibration

$$\begin{aligned} &\left(\sin\frac{\lambda}{2} \cosh\frac{\lambda}{2} - \cos\frac{\lambda}{2} \sinh\frac{\lambda}{2} \right) [(1 + \cos\beta\lambda \cosh\beta\lambda)\beta\lambda \\ &+ \alpha_1\beta^2\lambda^2(\cos\beta\lambda \sinh\beta\lambda - \sin\beta\lambda \cosh\beta\lambda)] \\ &+ 2k\lambda \sin\frac{\lambda}{2} \sinh\frac{\lambda}{2} [\sin\beta\lambda \cosh\beta\lambda + \cos\beta\lambda \sinh\beta\lambda \\ &+ \alpha_1\beta\lambda(\cos\beta\lambda \cosh\beta\lambda - 1)] = 0 \end{aligned} \quad (16.3)$$

The frequency equation may also be presented in terms of Hohenemser–Prager functions as follows (Anan'ev, 1946).

Symmetric vibration

$$EI_2 \sqrt[4]{\frac{m_2}{EI_2}} \frac{B(\lambda_2)}{D(\lambda_2)} = EI_1 \sqrt[4]{\frac{m_1}{EI_1}} \frac{C(\lambda_1)}{D(\lambda_1)} \quad (16.4)$$

where the relationship between frequency parameters is

$$\lambda_1 = \lambda_2 \frac{l}{2h} \sqrt[4]{\frac{m_1}{EI_2} \frac{EI_2}{m_2}} \quad (16.4a)$$

If $EI_1 = EI_2 = EI$ and $m_1 = m_2 = m$, then the frequency equation (16.4) becomes

$$\frac{B(\lambda_2)}{D(\lambda_2)} = \frac{C(\lambda_1)}{D(\lambda_1)}, \lambda_1 = \lambda_2 \frac{l}{2h}$$

Antisymmetric vibration

$$EI_2 \sqrt[4]{\frac{m_2}{EI_2}} \frac{\lambda_2 B(\lambda_2) - E(\lambda_2)}{D(\lambda_2) + A(\lambda_2)} = EI_1 \sqrt[4]{\frac{m_1}{EI_1}} \frac{S(\lambda_1)}{B(\lambda_1)} \quad (16.5)$$

16.1.2 Frame with clamped supports and lumped mass

Figure 16.2 shows a portal symmetric frame with clamped supports and one lumped mass. The distributed masses of the elements per unit length are m_1 and m_2 , lumped mass M is located at the middle span. The additional distributed loads carried by the horizontal and vertical elements are q_1 and q_2 , respectively (load q_2 is not shown). (Filippov, 1970.)

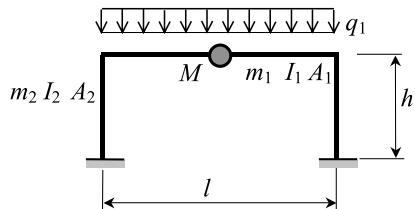

FIGURE 16.2. A portal symmetric frame with clamped supports and one lumped mass.

Exact solution. For the exact solution, the following non-dimensional parameters are used:

$$\begin{aligned} k &= \frac{I_1 h}{I_2 l}, \beta = \frac{h}{l} \sqrt[4]{\frac{A_2(1+e_2)I_1}{A_1(1+e_1)I_2}} \\ \alpha &= \frac{M}{(1+e_1)A_1\rho l}, \alpha_1 = \frac{M + A_1\rho l(1+e_1)}{A_2\rho h} \\ e_1 &= \frac{q_1}{g\rho A_1}, e_2 = \frac{q_2}{g\rho A_2} \\ \lambda^4 &= \frac{\rho A_1(1+e_1)l^4}{EI_1} \omega^2 \end{aligned}$$

The frequency of vibration may be calculated by formula (16.1), where λ is the roots of the frequency equation.

Frequency equation.

Symmetric vibration

$$\begin{aligned} \beta\lambda(\sin \beta\lambda \cosh \beta\lambda - \cos \beta\lambda \sinh \beta\lambda) &\left[\sin \frac{\lambda}{2} \cosh \frac{\lambda}{2} + \cos \frac{\lambda}{2} \sinh \frac{\lambda}{2} + \frac{\alpha\lambda}{2} \left(\cos \frac{\lambda}{2} \cosh \frac{\lambda}{2} - 1 \right) \right] \\ + k(1 - \cos \beta\lambda \cosh \beta\lambda) &\left[2\lambda \cos \frac{\lambda}{2} \cosh \frac{\lambda}{2} + \frac{\alpha\lambda^2}{2} \left(\cos \frac{\lambda}{2} \sinh \frac{\lambda}{2} - \sin \frac{\lambda}{2} \cosh \frac{\lambda}{2} \right) \right] = 0 \end{aligned} \quad (16.6)$$

Limiting case: If $h = 0$ or $I_2 = \infty$, then $k = 0$, $\beta = 0$ and frequency equation (16.6) becomes:

$$\sin \frac{\lambda}{2} \cosh \frac{\lambda}{2} + \cos \frac{\lambda}{2} \sinh \frac{\lambda}{2} + \frac{\alpha\lambda}{2} \left(\cos \frac{\lambda}{2} \cosh \frac{\lambda}{2} - 1 \right) = 0$$

which corresponds to a clamped-clamped beam with a lumped mass at the middle span (section 7.4, frequency equation is $D_2 = 0$).

Antisymmetric vibration

$$\begin{aligned} & \left(\sin \frac{\lambda}{2} \cosh \frac{\lambda}{2} - \cos \frac{\lambda}{2} \sinh \frac{\lambda}{2} \right) \\ & \times [(1 + \cos \beta \lambda \cosh \beta \lambda) \beta \lambda + \alpha_1 \beta^2 \lambda^2 (\cos \beta \lambda \sinh \beta \lambda - \sin \beta \lambda \cosh \beta \lambda)] \\ & \times 2k\lambda \sin \frac{\lambda}{2} \sinh \frac{\lambda}{2} [\sin \beta \lambda \cosh \beta \lambda + \cos \beta \lambda \sinh \beta \lambda + \alpha_1 \beta \lambda (\cos \beta \lambda \cosh \beta \lambda - 1)] = 0 \end{aligned} \quad (16.7)$$

Limiting case: if $h = 0$ or $I_2 = \infty$, then $k = 0$, $\beta = 0$ and the frequency equation (16.7) becomes:

$$\sin \frac{\lambda}{2} \cosh \frac{\lambda}{2} - \cos \frac{\lambda}{2} \sinh \frac{\lambda}{2} = 0$$

which corresponds to a clamped-pinned beam (the length of the span is $0.5l$) with a lumped mass at the pinned support (Table 5.3, position 3).

Approximate solution. The approximate solution may be obtained using the Rayleigh-Ritz method. The design diagram of the portal frame is presented in Fig. 16.2. The non-dimensional parameters, used for the approximate solution are:

$$\begin{aligned} k &= \frac{I_1 h}{I_2 l}, \beta = \frac{A_2 h}{A_1 l}, s = \frac{h}{l} \\ \alpha &= \frac{M}{\rho A_1 l} = \frac{M}{M_{\text{hor}}} \end{aligned}$$

where M is the concentrated mass, and M_{hor} is the mass of the horizontal bar.

Frequency equation*Symmetric vibration*

(a) If it is assumed that the shape of vibration corresponds to a uniformly distributed load, then the frequency of vibration equals

$$\omega = \sqrt{\frac{EI_1}{\rho Al^4}} \sqrt{\frac{1008(3k^2 + 7k + 2)}{(31k^2 + 22k + 4) + 12s^2 k^2 \beta + \frac{315}{128}(5k + 2)^2 \alpha}} \quad (16.8)$$

Example. Calculate the fundamental frequency of vibration for the frame if $I_1 = I_2$, $A_1 = A_2$, $h = l$, $M = 0$.

Solution. In this case $k = s = \beta = 1$, $\alpha = 0$ and the frequency of vibration occurs, and is obtained by the approximate solution

$$\omega = \frac{13.24}{l^2} \sqrt{\frac{EI_1}{\rho A}}$$

while the exact value of the natural frequency is

$$\omega = \frac{12.65}{l^2} \sqrt{\frac{EI_1}{\rho A}}$$

(b) If it is assumed that the shape of vibration corresponds to the concentrated load at the middle span then the frequency of vibration equals

$$\omega = \sqrt{\frac{EI_1}{\rho A_1 l^4}} \sqrt{\frac{6720(2k^2 + 5k + 4)}{(136k^2 + 117k + 26) + 48s^2 k^2 \beta + 70(2k + 1)^2 \alpha}} \quad (16.8a)$$

Antisymmetric vibration

If it is assumed that the shape of the vibration corresponds to a concentrated horizontal load, then the frequency of vibration is

$$\omega = \sqrt{\frac{EI_2}{\rho A_2 h^4}} \sqrt{\frac{210(18k^2 + 15k + 2)}{117k^2 + 123k + 33 + \frac{3}{4\beta s^2} + 17.5(2 + 3k)^2 \frac{1 + \alpha}{\beta}}} \quad (16.9)$$

16.1.3 Frame with haunched clamped supports

Figure 16.3 presents a portal frame with a broadening of the cross-sectional area at a zone of clamped supports and rigid joints. The parameters of the broadening are the same. The cross-bar of the frame is loaded by a uniformly distributed load q and lumped mass M .

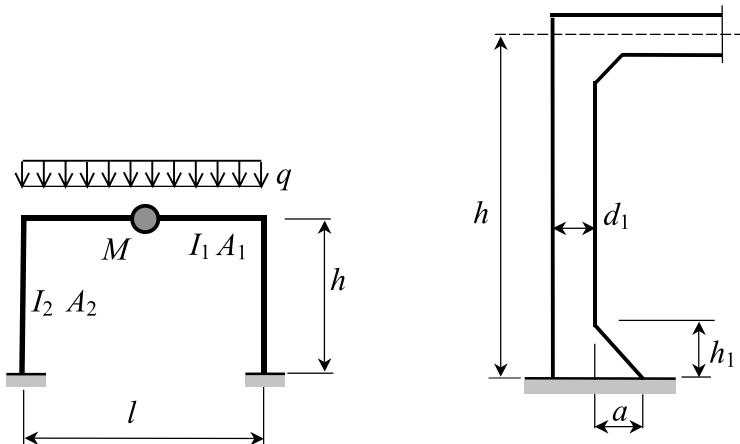

FIGURE 16.3. Portal frame with haunched clamped supports.

Non-dimensional parameters, used for the approximate solution are:

$$k = \frac{I_1 h}{I_2 l}, \beta = \frac{A_2 h}{A_1 l}, s = \frac{h}{l}$$

$$e = \frac{q}{g\rho A_1}, \alpha = \frac{M}{\rho A_1 l}$$

The approximate expressions for fundamental symmetric and antisymmetric frequencies of vibration have been obtained by the Rayleigh–Ritz method (Filippov, 1970).

Symmetric vibration

$$\omega = \frac{1}{l^2} \sqrt{\frac{EI_1}{\rho A_1} \sqrt{\frac{1008[3k^2 + (7 + a_1)k + 2]}{(31k^2 + 22k + 4)(1 + e) + 12s^2k^2\beta(1 + b_1) + 2.46(5k + 2)^2\alpha}}} \quad (16.10)$$

Antisymmetric vibration

$$\omega = \frac{\lambda}{h^2} \sqrt{\frac{EI_2}{\rho A_2}} \quad (16.11)$$

where the frequency parameter is

$$\lambda = \sqrt{\frac{210[(18 + a_4)k^2 + (15 + a_3)k + a_2 + 2]}{(117 + b_4)k^2 + b_2 + (123 + b_3)k + 33 + \frac{3}{4\beta s^2} + 17.5(2 + 3k)^2 \frac{1 + a}{\beta}}} \quad (16.11a)$$

The coefficients a_i and b_i for the various parameters of the broadening of the cross-sectional area are presented in Table 16.1.

16.1.4 Frame with hinged supports

Frame with a lumped mass. Figure 16.4 shows a two-hinged frame with one lumped mass; the distributed masses of elements are neglected. Mass M is located in the middle of the horizontal element.

Frequency vibration (exact solution). Assumption: longitudinal deformation of all members are neglected.

Symmetric vibration. In this case, mass M moves only in the vertical direction and the natural frequency is

$$\omega = \sqrt{\frac{48EI_1}{Ml^3} \frac{12k + 8\beta}{3k + 8\beta}} \quad (16.12)$$

where the dimensionless parameters are

$$k = \frac{l}{h}, \beta = \frac{I_1}{I_2}$$

	b_4	—	0.13	0.19	0.25	0.38	0.54	0.63

Parameters b_i , which are not presented in the table, are equal to zero.

Antisymmetric vibration. In this case, mass M moves only in the horizontal direction and the natural frequency is

$$\omega = \sqrt{\frac{12EI_1}{Mh^3} \frac{1}{2\beta + k}} \quad (16.13)$$

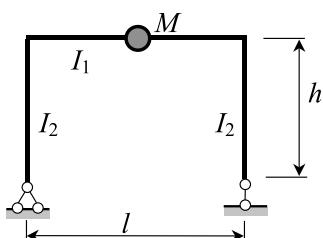

FIGURE 16.4. Frame with hinged supports and lumped mass.

Note. If $EI_1 = EI_2$ and ratio $(l/h)^2 = 240/11$, then the frequencies of vibration, which correspond to symmetrical and antisymmetrical modes of vibration of a frame, are equal.

Frame with distributed masses. A two-hinged symmetric portal frame with distributed masses m_1 and m_2 is presented in Fig. 16.5(a).

The exact solution for the given frame is based on the slope-deflection method (Chapter 4).

The primary system of the slope-deflection method is presented in Fig. 16.5(b). Imaginary constraint 1 prevents angular displacement, constraint 2 prevents both angular and linear displacements. Because the system is symmetric, symmetric and antisymmetric vibrations are considered separately.

Symmetric vibration. Unknown Z_1 of the slope-deflection method is the simultaneous symmetric rotation of constraints 1 and 2. The frequency equation is $r_{11} = 0$, where r_{11} is the reactive moment in the imaginary constraint 1 due to the simultaneous unit symmetric rotation of constraints 1 and 2. For calculation of r_{11} , consider the equilibrium of joint 1. The necessary formulas for reactive moments (Smirnov's function) in restriction 1 due to

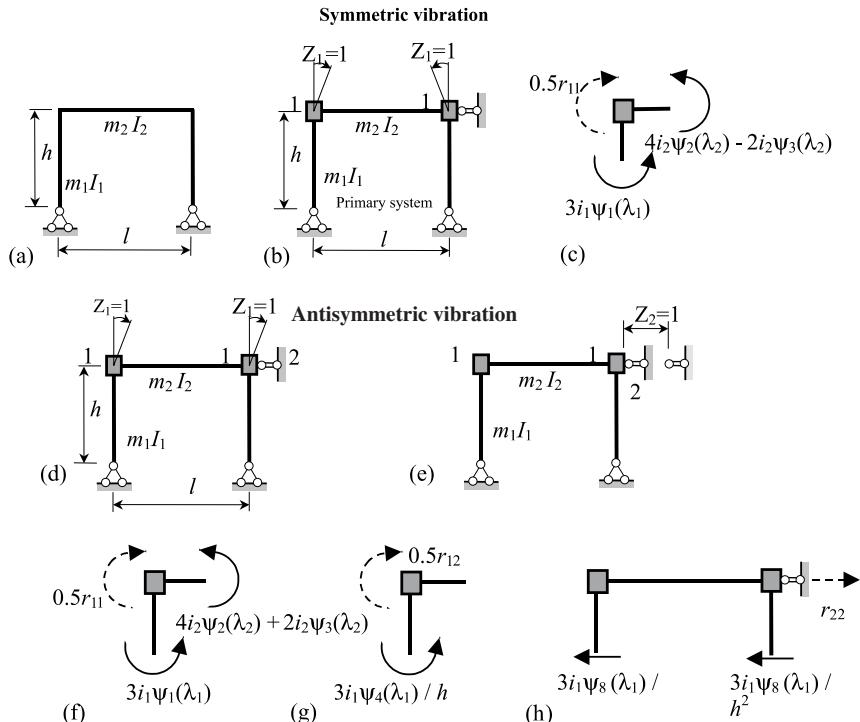

FIGURE 16.5. Symmetric two-hinged frame: (a) design diagram; (b,c) Symmetric vibration: primary system, unit group rotation $Z_1 = 1$ and equilibrium of the joint 1; (d-h) Antisymmetric vibration: (d-e) primary system, unit group rotation $Z_1 = 1$ and unit displacement $Z_2 = 1$; (f-g) equilibrium of the joint 1 due to $Z_1 = 1$ and $Z_2 = 1$; (h) equilibrium of the cross-bar.

the rotation of constraints 1 and 2 are presented in Table 4.4. The free body diagram of joint 1 is presented in Fig. 16.5(c). The equilibrium condition for joint 1 leads to the expression for the reaction

$$r_{11} = 2[3i_1\psi_1(\lambda_1) + 4i_2\psi_2(\lambda_2) - 2i_2\psi_3(\lambda_1)]$$

where i_1 and i_2 are bending stiffnesses per unit length for the first and second elements
 λ_1 and λ_2 are frequency parameters for the first and second elements
 ψ_1 , ψ_2 and ψ_3 are different types of Smirnov functions according to types of displacements and types of reactions (Table 4.4).

All terms in expression for r_{11} represent reactive moments, which arise in restriction 1.

The moment, represented by the first term, is created by bending the left vertical element due to the rotation of restriction 1 in the clockwise direction.

The moment, represented by the second term, is created by bending the horizontal element due to the rotation of restriction 1 in the clockwise direction.

The moment, represented by the third term, is created by bending of the horizontal element due to rotation of restriction 2 in the counterclockwise direction. Parameters λ_1 and λ_1 are related by formula (4.17).

Antisymmetric vibration. Unknown Z_1 in the slope-deflection method is the simultaneous antisymmetric rotation of joints 1 and 2; unknown Z_2 is the linear displacement of joints 1 and 2 in the horizontal direction. The frequency equation is

$$D = \begin{vmatrix} r_{11} & r_{12} \\ r_{21} & r_{22} \end{vmatrix} = 0$$

where r_{11} = reactive moment in the imaginary joint 1 due to the unit antisymmetric rotation of restrictions 1 and 2

r_{12} = reactive moment in the imaginary joint 1 due to the linear displacement of restriction 2 in the horizontal direction

r_{21} = reactive force in the imaginary restriction 2 due to the unit rotation of joints 1 and 2,

$r_{12} = r_{21}$ as reciprocal reactions (Section 2.1)

r_{22} = reactive force in the imaginary restriction 2 due to the unit linear displacement of restriction 2

Unit reactions are

$$r_{11} = 2[3i_1\psi_1(\lambda_1) + 4i_2\psi_2(\lambda_2) + 2i_2\psi_3(\lambda_2)]$$

$$r_{12} = r_{21} = 6i_1\psi_4(\lambda_1)/h$$

$$r_{22} = 6i_1\psi_8(\lambda_1)/h^2$$

Equation (16.4a) establishes the relationship between frequency parameters for vertical and horizontal elements. Condition $D = r_{11}r_{22} - r_{12}^2 = 0$ leads to a transcendental equation with respect to the frequency parameter.

For approximate solutions, all reactions r_{ik} for the element with specified boundary conditions in the primary system, may be taken from Table 4.7.

16.2 SYMMETRICAL T-FRAME

T-frames with clamped and pinned supports are presented in Figs. 16.6(a) and (b), respectively. Bending stiffness EI , length l , and mass m per unit length for all members are equal.

Antisymmetric and symmetric modes of in-plane transverse vibration have natural frequencies.

$$\omega = \frac{\lambda^2}{l^2} \sqrt{\frac{EI}{m}}$$

Frame with clamped supports

Antisymmetrical vibration. All members vibrate as a pinned-clamped beam. The frequency of vibration is $B(\lambda) = 0$, where B is the Hohenemser–Prager function. The roots of the frequency equation are

$$\lambda_1 = 3.9266, \lambda_2 = 7.0685, \dots, \lambda_n = \frac{4n+1}{4}\pi$$

Symmetrical vibration. Horizontal members vibrate as a clamped-clamped beam. The frequency of vibration is $D(\lambda) = 0$, where D is the Hohenemser–Prager function. The roots of the frequency equation are

$$\lambda_0 = 4.7300, \lambda_1 = 7.8532, \dots, \lambda_n \cong \frac{2(n+1)+1}{2}\pi$$

Corresponding numerical results are listed in Table 5.3.

Frame with pinned supports

Antisymmetrical vibration. All members vibrate as simply supported beams. The frequency of vibration is $\sin \lambda = 0$ (Table 5.3). The roots of the frequency equation are

$$\lambda_1 = \pi, \lambda_2 = 2\pi, \dots, \lambda_n = n\pi$$

Symmetrical vibration. Horizontal members vibrate as a pinned-clamped beam (Table 5.3).

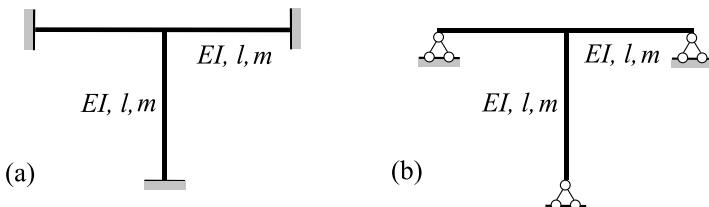

FIGURE 16.6. T-frame with (a) clamped supports, and (b) pinned supports.

16.3 SYMMETRICAL FRAMES

16.3.1 Properties of symmetrical systems

The purpose of this section is to show how to convert an initial symmetrical system into a half-system.

Symmetric system with an odd number of spans

1. In the case of symmetric vibrations, at the axis of symmetry,
 - (a) antisymmetric internal force (shear force) is zero;
 - (b) symmetrical displacements (horizontal and rotation) are zero.
2. In the case of antisymmetric vibrations, at the axis of symmetry,
 - (a) symmetric internal forces (bending moment and axial force) are zero;
 - (b) antisymmetric displacement (vertical) is zero.

In symmetrical systems the symmetric and antisymmetric vibration modes are determined independently.

Symmetric system with an even number of spans

1. In the case of symmetric vibrations, the central strut and a joint of the frame at the axis of symmetry, remain unmoved.
2. In the case of antisymmetric vibrations, the central strut of the frame may be presented as two struts, each having a bending stiffness equal to one half of the bending stiffness of the initial element.

These properties let us convert an initial symmetrical system into a half-system. The advantage of such a transformation is the decreasing of number of unknowns in the force or slope-deflection method (Darkov, 1989).

Table 16.2 shows the rules for conversion of an initial symmetric frame with odd or even numbers of spans corresponding to the half-frame.

Note

1. The rules presented in Table 16.2, are also applicable for multi-store frames.
2. Q , M and N are internal forces at the axis of symmetry.

16.3.2 Frames with infinite rigidity of the cross-bar

Symmetric one-store frames. This section presents portal one-span and multi-span one-store frames whose girders may be assumed to be infinitely rigid (very rigid in comparison with the rigidities of columns).

Case 1. The mass of the vertical strut is taken into account: m is the distributed mass per unit length; the mass of the horizontal cross-bar is neglected.

The frequency of horizontal vibration is

$$\omega_n = \frac{\lambda_n^2}{h^2} \sqrt{\frac{EI}{m}}$$

where the frequency equation and the parameters λ are presented in Table 16.3.

TABLE 16.2. Symmetric frame and corresponding half-frame for symmetric and antisymmetric vibrations

Number of spans	Symmetric vibrations	Antisymmetric vibrations
1,3,5,...		
	Half-frame	Half-frame
2,4,6,...		
	Half-frame	Half-frame

Case 2. The mass of the horizontal cross-bar is taken into account and the masses of the vertical struts are neglected (Bezukhov *et al.*, 1969) (see Table 16.4).

Case 3. The masses of the horizontal and vertical elements are taken into account (see Table 16.5).

Symmetric three-storey frame (Smirnov *et al.*, 1984). The masses of the horizontal elements are $2M$, $2M$ and M ; the masses of the vertical elements are neglected (Fig. 16.7).

The frequencies of horizontal vibration are

$$\omega_1 = \sqrt{1 - \frac{\sqrt{3}}{2} \sqrt{\frac{24EI}{h^3m}}}, \omega_2 = \sqrt{\frac{24EI}{h^3m}}, \omega_3 = \sqrt{1 + \frac{\sqrt{3}}{2} \sqrt{\frac{24EI}{h^3m}}} \quad (16.14)$$

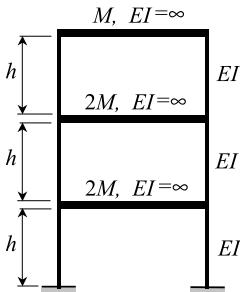

FIGURE 16.7. Symmetric three-storey frame.

The eigenvectors are

$$\theta_1 = \begin{bmatrix} 1 \\ \sqrt{3}/2 \\ 1/2 \end{bmatrix}, \theta_2 = \begin{bmatrix} 1 \\ 0 \\ -1 \end{bmatrix}, \theta_3 = \begin{bmatrix} 1 \\ -\sqrt{3}/2 \\ 1/2 \end{bmatrix} \quad (16.15)$$

The corresponding mode shapes are presented in Fig. 16.8.

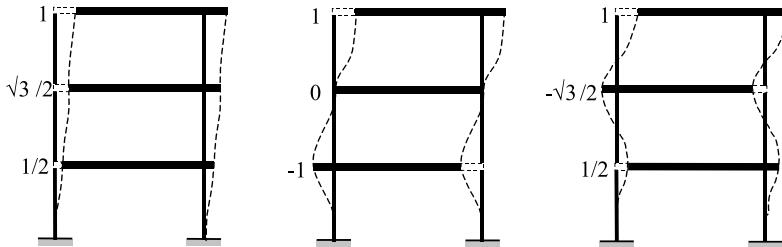

FIGURE 16.8. Mode shapes of the three-storey frame.

Quasi-regular multi-storey frames. Figure 16.9 presents multi-storey frames with infinite rigidity of all horizontal cross-bars.

The number of storeys is s , the height of each story is h , and the mass of the cross-bar with the mass of the columns of one storey is M . The total rigidity of all columns of one storey is EI .

Case 1. Masses of the girders are equal; bending stiffnesses of all struts are the same except for the first storey.

Case 2. Bending stiffnesses of all struts are the same; the masses of all girders are the same except for the last storey (Bezukhov *et al.*, 1969).

Case 1. Parameter u is the decreasing ($u > 0$) or increasing ($u < 0$) coefficient of bending stiffness for the lower strut. The frequency of vibration is

$$\omega = \lambda \sqrt{\frac{12EI}{h^3M}} \quad (16.16)$$

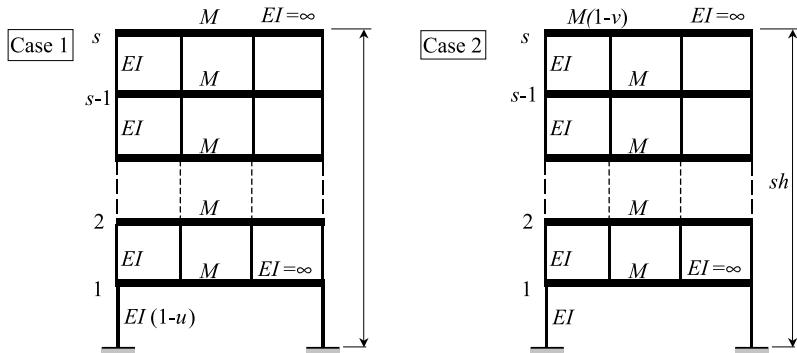

FIGURE 16.9. Quasi-regular multi-storey frames.

where $\lambda = 2 \sin \phi$ and ϕ is the root of the following equation:

$$\tan \phi \tan 2s\phi = \frac{1+u}{1-u} \quad (16.17)$$

Case 2. Parameter v is the decreasing ($v > 0$) or increasing ($v < 0$) coefficient of mass for the upper cross-bar. The frequency of vibration is determined by equation (16.16), where $\lambda = 2 \sin \phi$ and ϕ is root of the following equation

$$\tan \phi \tan 2s\phi = \frac{1}{1-2v} \quad (16.18)$$

16.4 VIADUCT FRAME WITH CLAMPED SUPPORTS

A symmetric viaduct frame is presented in Fig. 16.10. The bending stiffness and mass per unit length for all girders are EI_0 , m_0 , and for all struts are EI , m .

Natural frequencies of a viaduct frame in terms of the parameters of a strut are given by

$$\omega = \frac{\lambda^2}{h^2} \sqrt{\frac{EI}{m}}$$

The frequency parameter λ is the root of the frequency equation.

Antisymmetric vibration. The frequency equation is (Anan'ev, 1946)

$$\lambda^4 - \frac{1}{\mu} \left\{ 2R(\lambda) - \frac{L^2(\lambda)[2F(\lambda) + k(3F(\lambda_0) - H(\lambda_0))]}{(2F(\lambda) + kF(\lambda_0))[F(\lambda) + k(2F(\lambda_0) + H(\lambda_0))] - k^2H^2(\lambda_0)} \right\} = 0 \quad (16.19)$$

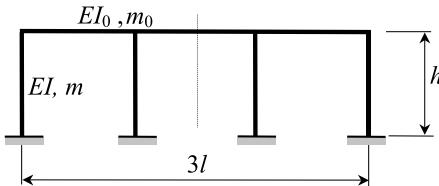

FIGURE 16.10. Viaduct frame with clamped supports.

where λ is the frequency parameter for the column (base frequency parameter), and λ_0 is the frequency parameter for the cross-bar. This parameter, in terms of the base element, is

$$\lambda_0 = \lambda \frac{l}{h} \sqrt[4]{\frac{m_0 EI}{m EI_0}}$$

Additional parameters are

$$k = \frac{hEI_0}{lEI}, \mu = \frac{3m_0l}{2hm}$$

Frequency functions R, L, F, H are as follows:

$$\begin{aligned} F(\lambda) &= \frac{\sin \lambda \cosh \lambda - \cos \lambda \sinh \lambda}{1 - \cos \lambda \cosh \lambda} \lambda \\ H(\lambda) &= \frac{\sinh \lambda - \sin \lambda}{1 - \cos \lambda \cosh \lambda} \lambda \\ L(\lambda) &= \frac{\sin \lambda \sinh \lambda}{1 - \cos \lambda \cosh \lambda} \lambda^2 \\ R(\lambda) &= \frac{\sin \lambda \cosh \lambda + \cos \lambda \sinh \lambda}{1 - \cos \lambda \cosh \lambda} \lambda^3 \end{aligned} \quad (16.20)$$

Special case. Let $k = 1$. In this case $\lambda_0 = \lambda$ and frequency equation (16.19) becomes:

$$\lambda^4 - \frac{1}{\mu} \left\{ 2R(\lambda) - \frac{L^2(\lambda)[5F(\lambda) - H(\lambda)]}{2F(\lambda)[3F(\lambda) + H(\lambda)] - H^2(\lambda)} \right\} = 0$$

The minimal root of the above equation is $\lambda = 1.70$.

Symmetric vibration. The frequency equation is

$$k[2F(\lambda_0) - H(\lambda_0)] + F(\lambda) - \frac{k^2 H^2(\lambda_0)}{F(\lambda) + kF(\lambda_0)} = 0 \quad (16.21)$$

Special case. Let $k = 1$. In this case $\lambda_0 = \lambda$ and frequency equation (16.21) becomes:

$$3F(\lambda) - H(\lambda) - \frac{H^2(\lambda)}{2F(\lambda)} = 0$$

The minimal root of the above equation is $\lambda = 3.4373$.

16.5 NON-REGULAR FRAME

This section provides a detailed example of the calculation of the natural frequency of vibration and the corresponding mode shape for a non-regular frame.

Example. The design diagram of a non-regular frame is presented in Fig. 16.11 (Smirnov et al., 1984). Element CD has an infinite bending rigidity.

Calculate the natural frequency of vibration and find the mode shape by using Bolotin's functions for the slope-deflection method.

Solution. Designate one of the elements as the base one and express the parameters of all other elements through the base one. Let element BC be the base one, then parameters i and k for other elements are presented in the following table.

Element	BC	AB	CD	BE
$i = EI/l$	i	$i/2$	∞	i
$k = m\omega^2 l^3$	k	$8k$	k	k

The primary system of the slope-deflection method is presented in Fig. 16.12. Imaginary restriction Z_1 prevents angular displacement of joint B and restriction Z_2 prevents the linear vertical displacement of point C.

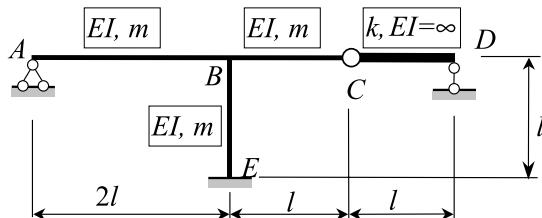

FIGURE 16.11. Design diagram of a non-regular frame.

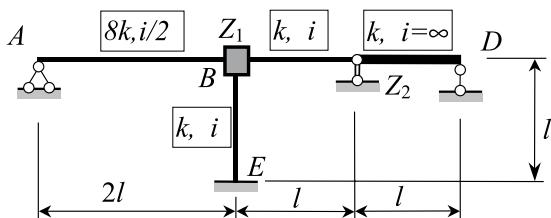

FIGURE 16.12. Primary system of slope-deflection method.

Canonical equations of the free vibration of the slope-deflection method are

$$\begin{bmatrix} r_{11} & r_{12} \\ r_{21} & r_{22} \end{bmatrix} \begin{bmatrix} Z_1 \\ Z_2 \end{bmatrix} = 0$$

Bending moment diagrams (M_1) due to unit angular displacement, and the diagram (M_2) due to unit linear vertical displacement, are shown in Fig. 6.13. The elastic curve is shown by the dotted line.

Bolotin's dynamic reactions due to the rotation of a fixed joint through angle $Z_1 = 1$ and linear vertical displacement $Z_2 = 1$ are as follows:

$$r_{11} = \left(3 \frac{i}{2} - \frac{2}{105} \cdot 8k \right) + \left(4i - \frac{k}{105} \right) + \left(3i - \frac{2k}{105} \right) = 8.5i - 0.181k$$

$$r_{22} = \left(\frac{3i}{l^2} - \frac{33k}{140l^2} \right) - \frac{k}{3l^2} = 3 \frac{i}{l^2} - 0.57 \frac{k}{l^2}$$

$$r_{12} = r_{21} = -\left(\frac{3i}{l} + \frac{11k}{280l} \right) = -\left(3 \frac{i}{l} + 0.04 \frac{k}{l} \right)$$

The canonical equations of the slope-deflection method are:

$$(8.5 - 0.181\mu)Z_1 - (3 + 0.04\mu)\frac{Z_2}{l} = 0$$

$$-(3 + 0.04\mu)Z_1 + (3 - 0.57\mu)\frac{Z_2}{l} = 0$$

$$\text{where } \mu = \frac{k}{i} = \frac{mc\omega^2 l^4}{EI}, \omega^2 = \frac{\mu EI}{ml^4}$$

The frequency equation is

$$(8.5 - 0.181\mu)(3 - 0.57\mu) - (3 + 0.04\mu)^2 = 0$$

or

$$0.101\eta^2 - 5.63\mu + 16.5 = 0$$

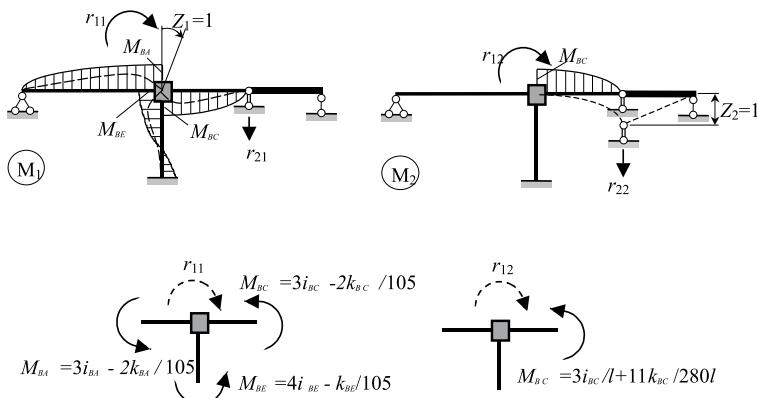

FIGURE 16.13. Bending moment diagrams due to unit displacements of additional restrictions and free body diagrams of the joints.

The roots of the frequency equation and the frequencies of vibrations are as follows (see Fig. 16.14)

$$\mu_1 = 3.1, \mu_2 = 52.5 \text{ and } \omega_1 = \sqrt{\frac{3.1EI}{ml^4}}, \omega_2 = \sqrt{\frac{52.5EI}{ml^4}}$$

Mode shape

$$Z_1 = \frac{3 + 0.04\mu}{8.5 - 0.181\mu} \frac{Z_2}{l}$$

Two modes shapes of vibration are presented in Fig. 16.14.
